3A.15.6 RESIDUAL SIGNIFICANT IMPACTS

Implementation of the Proposed Project or the other four action alternatives would result in significant impacts to numerous intersections and roadways. However, mitigation measures, including construction of roadway and intersection improvements, would reduce all but five of these impacts to a less-than-significant level. Five impacts would remain significant and unavoidable under the project plus cumulative scenario. Two intersection impacts, at Oak Avenue Parkway/East Bidwell Street and East Bidwell Street/Iron Point Road would remain significant and unavoidable because it is contrary to City policy to construct 8-lane roadways, as would be required to fully mitigate the impact. Impacts to three roadway segments on eastbound U.S. 50, including the Zinfandel Drive to Sunrise Boulevard segment, the Rancho Cordova Parkway to Hazel Avenue segment, and the Folsom Boulevard to Prairie City Road segment, would remain potentially significant and unavoidable. The mitigation measures proposed for these segments call for fair-share payments to support the construction of the Southeast Capitol Connector. However, based on available information, it cannot be determined that the proposed Southeast Capitol Connector would reduce traffic volumes on U.S. 50 to an acceptable LOS, and therefore these impacts are considered **significant and unavoidable** in this EIR/EIS.

The requirement that the project applicant(s) participate in funding transportation improvements outside the City of Folsom would mitigate or substantially lessen the remaining significant impacts on roadways outside of the City, but those impacts are still considered to be **significant and unavoidable**. This conclusion in part reflects the fact that, even with the installation of proposed improvements, some impacts would still remain significant because acceptable levels of service would not be achieved. This conclusion also reflects the fact that successful implementation of some of the proposed improvements would require the cooperation of third party agencies (Sacramento and El Dorado Counties, the City of Rancho Cordova, and Caltrans) over which the City of Folsom has no control on timing or implementation. For this latter reason, the City of Folsom is conservatively acknowledging the possibility that, despite its own commitment to work with these other agencies, mutually acceptable accommodation may not be reached. Consistent with the State CEQA Guidelines CCR Section 15091, subdivision (a)(2), though, the City of Folsom concludes that these other agencies can and should cooperate with the City in implementing the mitigation.

Project implementation would increase demand for single-occupant automobile travel on area roadways and intersections causing roadway and intersection impacts (Impact 3A.15-2). Implementation of Mitigation Measure 3A.15-2a would reduce the demand of the single-occupant vehicle on area roadways and intersections. Implementation of Mitigation Measures 3A.15-2b, 3A.15-2c, and 3A.15-2d would promote usage of alternative transportation modes and increase the supply of these modes. Although implementation of these mitigation measures have the potential to substantially reduce the number of single-occupant vehicles, the project would still add a large number of single-occupant vehicles in the area. Because there are no additional feasible mitigation measures to further reduce the number of project-generated single-occupant vehicle trips, the impact would be significant and unavoidable.

This section was prepared by RMC Water and Environment.

3B.15 TRAFFIC AND TRANSPORTATION – WATER

3B.15.1 AFFECTED ENVIRONMENT

This discussion places an emphasis on describing the affected environment for locations where physical environmental impacts would occur as a result of the construction and operation of the Off-site Water Facilities. In this context, the discussion is focused to portions of Zone 4 of the overall "Water" Study Area.

ROADWAY NETWORK

Affected roadways within Zone 4 of the "Water" Study Area fall under the jurisdiction of Sacramento County or the City of Rancho Cordova. These roadways are illustrated in Exhibit 2-26 in Chapter 2, "Alternatives." A brief description of key roadways in Zone 4 of the "Water" vicinity is provided below.

- **Sunrise Boulevard** is a major north-south secondary (arterial) road that connects Grant Line Road to the City of Roseville. It has two lanes between Grant Line Road and Douglas Road, four lanes between Douglas Road and White Rock Road, and six lanes north of White Rock Road.

- **White Rock Road** extends from International Drive to El Dorado County and is a two-lane roadway east of Sunrise Boulevard. In the vicinity of Zone 4 of the "Water" Study Area, the Circulation Element in the City of Rancho Cordova General Plan designates this roadway as a six-lane expressway. The widening of White Rock Road from Sunrise Boulevard to the future Silva Valley interchange in El Dorado Hills is a fully funded project.

- **Folsom Boulevard** is a four-lane secondary (arterial) road that extends from the City of Sacramento, through the City of Rancho Cordova and Sacramento County, into the City of Folsom. It is a four-lane roadway within the vicinity of Zone 4 of the "Water" Study Area.

- **Douglas Road** is a two-lane roadway that extends from Mather Boulevard in the Mather Reuse Area to Grant Line Road. The Circulation Element of the City of Rancho Cordova's General Plan designates this roadway as a six-lane major road.

- **Excelsior Road** is a two-lane roadway that extends Grant Line Road north to Mather Road through central Sacramento County.

- **Eagles Nest Road** is a two-lane roadway that extends Grant Line Road north to Douglas Road through central Sacramento County. Eagles Nest Road parallels Excelsior Road to the east. A portion of this roadway is currently unimproved (unpaved).

- **Mather Boulevard** is a two-lane roadway that extends to the northern terminus of Excelsior Road north to Mather Field Road.

- **Grant Line Road** is a two-lane roadway that extends from SR 99 to White Rock Road through the southeastern portion of Sacramento County. The County and City of Rancho Cordova General Plans designate this roadway as a six-lane expressway. This roadway is currently the preferred alignment for the East County Connector.

- **Jackson Highway**, also known as SR 16, is a two-lane highway that extends from Folsom Boulevard east of Howe Avenue into Amador County. In the vicinity of the Off-site Water Facilities Study Area, the Circulation Element of the City of Rancho Cordova General Plan designates this roadway as a six-lane expressway.

- **Prairie City Road** is a rural, two-lane road south of U.S. 50 to its terminus at White Rock Road.

- **Gerber Road** is an east-west, 2-lane, rural roadway in the southern portion of Zone 4 of the "Water" Study Area.

- **Ivan Way** is a north-south, residential collector roadway within the North Douglas Community.

Planned Roadways

- **Rancho Cordova Parkway (Planned).** This roadway would run north-south and provide connectivity between White Rock Road and a new interchange on U.S. 50. The planned roadway cross-section would include six vehicle travel lanes, bicycle lanes, a landscaped median and landscape corridors with sidewalks on both sides. This roadway would serve as the primary north-south connector for the City of Rancho Cordova east of Sunrise Boulevard and would be constructed in conjunction with the planned Westborough Specific Plan area.

- **Easton Valley Parkway (Planned).** This roadway is proposed to run east-west and begin at the intersection with the planned Rancho Cordova Parkway. The planned roadway cross-section would include up to six vehicle travel lanes, bicycle lanes, a landscaped median, and landscape corridors with sidewalks on both sides. This roadway would provide parallel capacity for U.S. 50, intersect with a future extension of Hazel Avenue, continue through the planned Easton Place and Glenborough developments, and may ultimately extend across Prairie City Road into the Folsom SPA.

LEVEL OF SERVICE

Level of Service (LOS) is a general measure of traffic operating conditions whereby a letter grade, from A (the best) to F (the worst), is assigned. These grades represent the perspective of drivers and are an indication of the comfort and convenience associated with driving. The LOS grades are defined in the Highway Capacity Manual (HCM) as follows:

- LOS A represents free-flow travel with an excellent level of comfort and convenience and the freedom to maneuver.

- LOS B has stable operating conditions, but the presence of other road users causes a noticeable, though slight, reduction in comfort, convenience, and maneuvering freedom.

- LOS C has stable operating conditions, but the operation of individual users is significantly affected by the interaction with others in the traffic stream.

- LOS D represents high-density, but stable flow. Users experience severe restriction in speed and freedom to maneuver, with poor levels of comfort and convenience.

- LOS E represents operating conditions at or near capacity. Speeds are reduced to a low but relatively uniform value. Freedom to maneuver is difficult with users experiencing frustration and poor comfort and convenience. Unstable operation is frequent, and minor disturbances in traffic flow can cause breakdown conditions.

- LOS F is used to define forced or breakdown conditions. This condition exists wherever the volume of traffic exceeds the capacity of the roadway. Long queues can form behind these bottleneck points with queued traffic traveling in a stop-and-go fashion.

Existing Roadway Conditions

The City conducted a review of several recently prepared EIRs (City of Rancho Cordova 2006 and Sacramento County 2008b) for development projects within Zone 4 of the "Water" Study Area, both certified and in public draft form, to establish a baseline for existing roadway operations. Roadways considered as part of this analysis and their current average daily trips (ADT) and LOS are provided in Table 3B.15-1.

Table 3B.15-1
Level of Service for Roadways in Zone 4 of the "Water" Study Area

Roadway Segment	Average Daily Trips	Level of Service (Peak Hour)
Sunrise Boulevard (White Rock Road to Douglas Road)	24,600	B
Sunrise Boulevard (Florin Road to Grant Line Road)	7,300	D
Grant Line Road (White Rock Road to Douglas Road)	9,600	D
Grant Line Road (Douglas Road to SR 16)	7,300	D
Grant Line Road (SR 16 to Sunrise Boulevard)	5,600	C
Folsom Boulevard (Hazel Avenue to Sunrise Boulevard)	13,300	A
Prairie City Road (U.S. 50 to White Rock Road)	5,800	A
Douglas Road (Grant Line Road to Sunrise Boulevard)	2,300	A
Douglas Road (Mather to Sunrise Boulevard)	5,000	A
White Rock Road (Sunrise Boulevard to Grant Line Road)	13,900	B
White Rock Road (Grant Line Road to Prairie City Road)	10,300	E
White Rock Road (Grant Line Road to Scott Road)	7,600	D
Excelsior Road (segment not specified)	3,908	A
Eagles Nest Road (segment not specified)	NA	NA
Florin Road (east of Bradshaw Road)	3,050	B
Gerber Road (east of Bradshaw Road)	7,349	C

Note: NA = not applicable
Source: Sacramento County 2008b, City of Rancho Cordova 2006

BIKEWAYS

The 2010 Sacramento City/County Bikeway Master Plan (Sacramento County 1992) identifies existing and planned bicycle routes through Zone 4 of the "Water" Study Area. The only existing facility in the Zone 4 is an off-street multiuse path along the FSC west of Sunrise Boulevard, connecting Hazel Avenue north of U.S. 50 with Grant Line Road. In addition to this facility, on-street bike lanes are planned on Sunrise Boulevard, Grant Line Road, Jackson Highway (SR 16) (just past Grant Line Road), Kiefer Boulevard west of Sunrise Boulevard, Douglas Road west of Sunrise Boulevard, Excelsior Road, and White Rock Road. The City/County Bikeway Master Plan also contains design, safety, and traffic control standards for use in constructing and upgrading facilities. The County is currently in the process of updating their Bikeway Master Plan.

RAIL SERVICE

Rail service in eastern Sacramento County is limited to freight service. There is no direct rail passenger service.

TRANSIT SYSTEM

Light-rail transit service is provided from downtown Sacramento along the U.S. 50 corridor to the Hazel Avenue light-rail station. Light rail then extends eastward to the City of Folsom. Another light-rail station is being proposed as part of the Westborough Specific Plan area and would be located between the Sunrise Boulevard station and the Hazel Avenue station.

EMERGENCY VEHICLE ACCESS

The Sacramento Metropolitan Fire District operates five fire stations within Zone 4 of the "Water" Study Area. The fire stations include Stations 50, 55, 58, 61, and 66, which are located at 8880 Gerber Road, 7776 Excelsior Road, 7520 Sloughhouse Road, 10595 Folsom Boulevard, and 3180 Kilgore Road, respectively.

3B.15.2 REGULATORY FRAMEWORK

FEDERAL PLANS, POLICIES, REGULATIONS, AND LAWS

There are no Federal plans, policies, regulations, or laws related to traffic and transportation that apply to the Off-site Water Facility Alternatives under consideration. Federal regulations that apply to traffic and transportation are administered by Caltrans and local jurisdictions.

STATE PLANS, POLICIES, REGULATIONS, AND LAWS

Caltrans prepares a Transportation Concept Report for each of its facilities in Zone 4 of the "Water" Study Area. A Transportation Concept Report is a long-term planning document that each Caltrans district prepares for every state highway or portion thereof in its jurisdiction. This document usually represents the first step in Caltrans' long-range corridor planning process. The purpose of a Transportation Concept Report is to determine how a highway will be developed and managed so that it delivers the targeted LOS and quality of operations that are feasible to attain over a 20-year period. These are indicated in the "route concept." In addition to the 20-year route concept level, the Transportation Concept Report includes an "ultimate concept," which is the ultimate goal for the route beyond the 20-year planning horizon. Ultimate concepts must be used cautiously, however, because unforeseen changes in land use and other variables make forecasting beyond 20 years difficult.

SR 16 crosses the southern portion of Zone 4 of the "Water" Study Area and has a route concept level of LOS E. The ultimate concept for SR 16 is a four-lane facility with continuous left-turn lanes (Caltrans 2004a).

REGIONAL AND LOCAL PLANS, POLICIES, REGULATIONS, AND LAWS

The following local and regional plans, policies, regulations, and laws related to transportation and alternative transportation are relevant to the Off-site Water Facilities alternatives, and are described in detail in Section 3A.15, "Traffic and Transportation – Land:"

- Metropolitan Transportation Plan for 2035 (MTP 2035)
- City of Folsom General Plan
- Sacramento County General Plan
- City of Rancho Cordova General Plan

Sacramento County

According to the Policy CI-22 of the Sacramento County General Plan, the County applies the following LOS standards for planning roads within unincorporated areas:

1. Rural collectors: LOS D
2. Urban area roads: LOS E

City of Rancho Cordova Capital Improvement Program

The City of Rancho Cordova has been operating under a 5-year Capital Improvement Program (CIP) (2005–2010) that includes several roadway facilities in Zone 4 of the "Water" Study Area, including improvements to Douglas Road, Kiefer Boulevard, Sunrise Boulevard, and SR 16. Funding sources associated with the current CIP include development fees, financing districts, Measure A sales taxes[1], and state and Federal funding sources.

3B.15.3 Environmental Consequences and Mitigation Measures

Thresholds of Significance

The thresholds for determining the significance of impacts for this analysis are based on the environmental checklist in Appendix G of the State CEQA Guidelines. These thresholds also encompass the factors taken into account under NEPA to determine the significance of an action in terms of its context and the intensity of its impacts. For the purposes of this analysis, to determine whether traffic and transportation impacts are significant environmental effects, the following questions are analyzed and evaluated. Would the project:

- cause an increase in traffic, which is substantial in relation to the existing traffic load and capacity of the street system (i.e., result in a substantial increase in either the number of vehicle trips, the volume to capacity ratio on roads, or congestion at intersections);
- exceed, either individually or cumulatively, a level of service standard established by the county congestion management agency for designated roads or highways;
- result in a change in air traffic patterns, including either an increase in traffic levels or a change in location that results in substantial safety risks;
- substantially increase hazards due to a design feature (e.g., sharp curves or dangerous intersections) or incompatible uses (e.g., farm equipment);
- result in inadequate emergency access;
- result in inadequate parking capacity; or
- conflict with adopted policies, plans or programs supporting alternative transportation (e.g., bus turnouts, bicycle racks).

Analysis Methodology

The operations of roadway facilities are described in terms of LOS. LOS is a qualitative description of traffic flow based on factors such as speed, travel time, delay, freedom to maneuver, volume, and capacity. Six levels are

[1] Measure A is a half-cent sales tax that was approved by voters to implement transportation improvements in the Sacramento region. Some Measure A funding has been identified to fund specific roadway improvements in the project study area.

defined, from LOS A, as the best operating conditions, to LOS F, or the worst operating conditions, as described in the setting discussion. LOS E represents "at-capacity" operations. When volumes exceed capacity, stop-and-go conditions result and operations are designated as LOS F.

Because the Off-site Water Facility Alternatives under consideration would cause traffic impacts on roadways that are under state, County, and City of Rancho Cordova jurisdictions, this analysis considers a combination of policies and guidelines. The City of Rancho Cordova identifies LOS D as its minimum standard for intersection operations. The County identifies LOS E as the minimum acceptable standard for intersection operations in the project vicinity. For state-controlled facilities, thresholds presented in the State's Route Concept Report were applied (e.g., the concept service level for SR 16 is LOS E).

Program-level impacts for the Off-site Water Facility Alternatives and mitigation measures are presented together in the section below. Operational impacts to the roadway network were assessed in relation to the total number of daily vehicle trips generated by the WTP, which as provided in Chapter 2, "Alternatives," could be up to 40 daily vehicle trips and that access would occur from White Rock Road. These operational trips are included in the overall traffic analysis provided in Section 3A.15, "Traffic and Transportation – Land," which provides an analysis of overall build-out of Folsom SPA and was considered appropriate given that the Off-site Water Facility Alternatives would only be constructed in conjunction with the approval Folsom South of 50 Specific Plan. However, since the Off-site Water Facilities would need to be constructed and operational in advance of the occupancy of any commercial or residential structures within the Folsom SPA, this analysis considers the addition of this vehicles trips prior to any build-out within the SPA.

ISSUES NOT DISCUSSED FURTHER IN THIS EIR/EIS

Safety Hazards from Change in Air Traffic Patterns—The Off-site Water Facility Alternatives would not include the construction of any structural facilities within a runway hazard or overflight zone. Likewise, the Off-site Water Facility Alternatives would not include the expansion of airport facilities or increase air traffic. In this context, the Off-site Water Facility Alternatives would not require a change in air traffic patterns, including either an increase in traffic levels or a change in location that results in substantial safety risks. No impact would occur. Therefore, this issue area is not discussed further.

Alternative Forms of Transportation—The Off-site Water Facility Alternatives would not involve new land development that would place new demands on alternative forms of transportation. For this reason, the Off-site Water Facility Alternatives would not include any actions that would conflict with adopted policies, plans or programs supporting alternative transportation (e.g., bus turnouts, bicycle racks). Issues related to potential temporary conflicts between Off-site Water Facility Alternatives construction and existing bicycle or pedestrian trails are addressed in Section 3B.12, "Parks and Recreation – Water." No impact would occur. Therefore, this issue area is not discussed further.

Parking Capacity—Construction worker parking would be available at designated staging areas and along local roadways where sufficient space along the roadway shoulder is available. As provided in Chapter 2, "Alternatives," the Off-site Water Facility Alternatives would not involve the construction of new commercial or residential uses and, therefore, no new increased demand for parking would directly result in response to the Off-site Water Facility Alternatives. Sufficient employee parking would be provided on-site at the WTP, if constructed. Based on these considerations, the Off-site Water Facility Alternatives is not expected to result in inadequate parking capacity and no impact would occur. Therefore, this issue area is not discussed further.

IMPACT ANALYSIS

Impacts that would occur under each of the Off-site Water Facility Alternatives are identified as follows:

NCP (No USACE Permit Alternative)

PA (Proposed Off-site Water Facility Alternative)

1 (Off-site Water Facility Alternative 1 – Raw Water Conveyance – Gerber/Grant Line Road Alignment and White Rock WTP)

1A (Off-site Water Facility Alternative 1A Raw Water Conveyance – Gerber/Grant Line Road Alignment Variation and White Rock WTP)

2 (Off-site Water Facility Alternative 2 Treated Water Conveyance – Douglas Road Alignment and Vineyard SWTP)

2A (Off-site Water Facility Alternative 2A Treated Water Conveyance – Excelsior Road Alignment Variation and Vineyard SWTP)

2B (Off-site Water Facility Alternative 2B Treated Water Conveyance – North Douglas Tanks Variation and Vineyard SWTP)

3 (Off-site Water Facility Alternative 3 Raw Water Conveyance – Excelsior Road Alignment and White Rock WTP)

3A (Off-site Water Facility Alternative 3A Raw Water Conveyance – Excelsior Road Alignment Variation and White Rock WTP)

4 (Off-site Water Facility Alternative 4 Raw Water Conveyance – Easton Valley Parkway Alignment and Folsom Boulevard WTP)

4A (Off-site Water Facility Alternative 4A Raw Water Conveyance – Easton Valley Parkway Alignment Variation and Folsom Boulevard WTP).

The impacts for each alternative are compared relative to the PA at the end of each impact conclusion (i.e., similar, greater, lesser).

IMPACT 3B.15-1 Temporary and Short-Term Reduction in Roadway Capacity during Construction. *Off-site Water Facility Alternatives construction could result in temporary reductions in roadway capacities, which could be substantial in relation to existing volume-to-capacity ratios on local roadways and congestion at intersections.*

NCP, PA, 1, and 1A

Under these alternatives, construction-generated traffic would be temporary, approximately 36 months in duration, and therefore would not result in any long-term degradation in operating conditions or LOS on any roadways within the Zone 4 of the "Water" Study Area. The primary impacts from Off-site Water Facilities construction vehicle traffic would include temporary, short-term, and intermittent reductions of roadway capacities associated with the movement of construction equipment. Lane blockage caused by construction traffic would be temporary and limited to within the immediate vicinity of pipeline construction.

Pipeline construction would affect the roadway network in two ways. Construction would either cross a roadway or it would run parallel to a roadway within the public right-of-way. As proposed, these Off-site Facility Alternatives pipeline would run parallel to or longitudinally within the public road right-of-way and, as a result, portions of the roadway that would normally be used for traffic circulation or parking would be temporarily unavailable. This displacement could block two travel lanes, one travel lane and the adjacent shoulder/parking area, or just the shoulder/parking area, depending upon the pipeline's lateral placement within the road right-of-

way. It is estimated that lane blockages would last for durations varying between a few days for perpendicular encroachments to 2–3 weeks for parallel or longitudinal encroachments at any given segment of Grant Line Road, Gerber Road, and White Rock Roads. These **direct** and **indirect** impacts are considered **potentially significant**. ***[Similar]***

In addition to the above impacts, the use of large trucks to transport equipment and material to and from the Off-site Water Facilities work site could affect road conditions on the access routes by increasing the rate of road wear. The degree to which this impact would occur depends on the design (pavement type and thickness) and the existing condition of the road. Major arterials and collectors are designed to accommodate a mix of vehicle types, including heavy trucks. The potential impacts are expected to be negligible on those roads. However, lower-capacity roadways could be significantly impacted by construction equipment within the roadway. Therefore, this **direct** impact is considered **significant**. ***[Similar]***

Mitigation Measure 3B.15-1a: Prepare Traffic Control Plan.

Prior to construction, the City shall prepare a Traffic Control Plan for roadways and intersections affected by Off-site Water Facilities-related construction. The Traffic Control Plan shall designate haul routes and comply with requirements in the encroachment permits issued by the City of Rancho Cordova, Sacramento County, and Caltrans. The Traffic Control Plan to be prepared by the construction contractor(s) shall, at minimum, include the following measures:

- Maintaining the maximum amount of travel lane capacity during non-construction periods, possible, and advanced notice to drivers through the provision of construction signage.
- Maintaining alternate one-way traffic flow past the lay down area and site access when feasible.
- Heavy trucks and other construction transport vehicles shall avoid the busiest commute hours (7 a.m. to 8 a.m. and 5 p.m. to 6 p.m. on weekdays).
- The City shall provide a minimum 72-hour advance notice of access restrictions for residents, businesses, and local emergency response agencies. This shall include the identification of alternative routes and detours to enable for the avoidance of the immediate construction zone.
- The City, in cooperation with its contractor(s), shall provide a phone number and community contact for inquiries about the schedule of the Off-site Water Facilities throughout the construction period. This information will be posted in a local newspaper, via the City's web site, or at City Hall and will be updated on a monthly basis.
- To the extent practical depending the alignment of the selected Off-site Water Facility Alternative, the City shall maximize opportunities for coordinated construction and installation of the conveyance pipeline with other planned roadway improvement projects.

Implementation: City of Folsom Utilities Department

Timing: Prior to and during construction of all Off-site Water Facilities

Enforcement:

1. For structural improvements that would be located within the City of Folsom: City of Folsom Neighborhood Services Department and City of Folsom Community Development Department.
2. For structural improvements that would be located within unincorporated Sacramento County: Sacramento County Planning and Community Development Department.

3. For structural improvements that would be located within the City of Rancho Cordova: City of Rancho Cordova Planning Department.

Mitigation Measure 3B.15-1b: Assess Pre-Off-site Water Facilities Roadway Conditions.

Prior to construction, the City's construction contractor(s) shall be responsible for assessing current road conditions for Off-site Water Facilities-related haul routes including the local access roads and develop post construction road restoration requirements. As part of the encroachment permitting process, an agreement shall be entered into with applicable jurisdictions prior to construction that details post construction road restoration requirements. Staff with the City of Rancho Cordova and Sacramento County shall review the post construction restoration standards for each of the affected roadways. The City shall perform roadway repairs or rehabilitation as necessary such that post construction requirements are met.

Implementation: City of Folsom Utilities Department

Timing: Prior to and during construction of all Off-site Water Facilities

Enforcement:

1. For structural improvements that would be located within the City of Folsom: City of Folsom Neighborhood Services Department and City of Folsom Community Development Department.

2. For structural improvements that would be located within unincorporated Sacramento County: Sacramento County Planning and Community Development Department.

3. For structural improvements that would be located within the City of Rancho Cordova: City of Rancho Cordova Planning Department.

2, 2A, and 2B

Traffic-related impacts to roadways would be similar under Alternatives 2 and 2A to those described for Off-site Water Facility Alternative 1. Under Off-site Water Facility Alternatives 2 and 2A, these impacts would be shifted to Vineyard Road, Eagles Nest Road, Douglas Road, and White Rock Road. Under Off-site Water Facility Alternative 2A, the alignment would be shifted from Eagles Nest Road (Off-site Water Facility Alternative 2) to Excelsior Road which has a higher ADT. Under Off-site Water Facility Alternative 2B, the shortened alignment would only impact Ivan Way, Douglas Road, and White Rock Road. Nevertheless, these alternatives could result in similar roadway construction impacts as identified for the Proposed Off-site Water Facility Alternative, and the **direct** and **indirect** impacts would be considered **potentially significant**. ***[Similar]***

Mitigation Measure: Implement Mitigation Measures 3B.15-1a and 3B.15-1b.

3 and 3A

Traffic-related impacts to roadways would be similar under Alternatives 3 and 3A to those described for Off-site Water Facility Alternative 1. Under Alternatives 3 and 3A, these impacts would be shifted to Vineyard Road, Eagles Nest Road, Douglas Road, and White Rock Road. Under Alternative 3A, the alignment would be shifted from Eagles Nest Road (Off-site Water Facility Alternative 3) to Excelsior Road which has a higher ADT. These alternatives could result in similar roadway construction impact as identified for the Proposed Off-site Water Facility Alternative, and **direct** and **indirect** impacts would be considered **potentially significant**. ***[Similar]***

Mitigation Measure: Implement Mitigation Measures 3B.15-1a and 3B.15-1b.

4 and 4A

Traffic-related impacts to roadways would be similar under Off-site Water Facility Alternatives 4 and 4A to those described for Off-site Water Facility Alternative 1. Under Off-site Water Facility Alternatives 4 and 4A, these impacts would be shifted to Vineyard Road, Eagles Nest Road, Douglas Road, White Rock Road, and potentially, Sunrise Boulevard. Under Off-site Water Facility Alternative 4A, the alignment would be shifted from Eagles Nest Road (Off-site Water Facility Alternative 2) to Excelsior Road which has a higher ADT. These alternatives could result in similar roadway construction impact as identified for the Proposed Off-site Water Facility Alternative, and **direct** and **indirect** impacts would be considered **potentially significant**. ***[Similar]***

Mitigation Measure: Implement Mitigation Measures 3B.15-1a and 3B.15-1b.

Implementation of Mitigation Measures 3B.15-1a and 3B.15-1b would ensure that temporary and short-term impacts to traffic and roadway LOS would be reduced to a **less-than-significant** level by ensuring the continued movement of traffic during construction, minimizing disruption to adjacent residences and bike access, and providing sufficient notification to the affected population of alternate travel routes.

IMPACT 3B.15-2 Exceedance of Established Level of Service Standards for Local Roadways. *The implementation of Off-site Water Facility Alternatives could cause traffic conditions to exceed, either individually or cumulatively, a level of service standard established by the County congestion management agency for designated roads or highways.*

NCP, PA, 1, 1A, 2, 2A, 2B, 3, 3A, 4, and 4A

During construction, traffic would be generated from two sources: truck trips to and from the work site, and construction work crews and supervisor staff commuting to and from the work site. Based on a maximum of three construction crews, the maximum number of crew members accessing portions of Zone 4 of the "Water" Study Area at any one time would be up to 66 individuals or up to 66 additional vehicle trips per day for both the morning and evening peak hours. In addition, during peak excavation and earthwork activities, the Off-site Water Facility Alternatives could generate up to 20 round-trip truck trips per day. However, average daily earthwork truck trips would be less and range from about 1 to 4 round trips per day during much of construction and could be scheduled to avoid the peak traffic hours. Additional trips to or from the construction site would occur during project initiation with the delivery of various equipment to the site such as excavators, tracked excavators, wheel loaders, concrete pump trucks, graders, backhoes and other equipment (see Chapter 2, "Alternatives"). All construction-generated fill and excavated spoils would be used as fill material for the WTP site or transported to the Kiefer Landfill for disposal. For this reason, it is reasonable to conclude that no transportation of fill to areas outside of Zone 4 of the "Water" Study Area would occur in conjunction with the Off-site Water Facility Alternatives.

If all the construction-related equipment and the construction crews accessed or exited the site during the evening peak-hour the maximum number of vehicles would be up to 86 at any one time. In recognizing the poor operating conditions on portions of local roadways during the peak traffic hours (e.g., Sunrise Boulevard), the addition of project-related construction traffic could temporarily lead to further degradation in traffic movements. **Potentially significant direct** and **indirect** transportation impacts associated with the Off-site Water Facilities would occur. ***[Similar]***

As provided in Chapter 2, "Alternatives," the operation of the WTP under any of the alternatives are expected to require up to 10 employees, on average, each of which could produce 4 daily vehicle trips for a total of 40 daily trips or less. Given that these trips would be dispersed throughout the day and the roadway network, they would not be expected to not result in any long-term degradation in operating conditions or LOS on any local roadways

or intersections. For these reasons, long-term, **direct** and **indirect** traffic-related impacts associated with the Off-site Water Facility Alternative are considered **less than significant**. ***[Similar]***

Mitigation Measure: Implement Mitigation Measure 3B.15-1a.

Implementation of Mitigation Measure 3B.15.1a would ensure that temporary and short-term impacts to roadway and intersection LOS would be reduced to a **less-than-significant** level by ensuring the continued movement of traffic past the construction zone and provision of alternative routes. Because of the low volume of daily trips generated by the combined operation of the Off-site Water Facility Alternatives, a **less than significant**, long-term operational impact is expected.

IMPACT 3B.15-3 Increased Traffic Hazards on Local Roadways. *Implementation of the Off-site Water Facility Alternatives could substantially increase hazards on local roadways due to the presence of incompatible uses, such as construction equipment.*

NCP, PA, 1, 1A, 2, 2A, 2B, 3, 3A, 4, and 4A

Haul trucks and heavy equipment used during the construction of the Off-site Water Facilities would interact with vehicle movements on existing roadways. The creation of a construction work zone on high-volume or high-speed roadways would increase the potential for traffic safety hazards because of the need to safely transition traffic into the travel lane(s) adjacent to the work zone. Because of the temporary disruption to traffic flow, the removal of lanes, the presence of construction equipment in the public right-of-way, and the localized increase in traffic congestion, drivers would be presented with unexpected driving conditions and obstacles. This could potentially result in an increased occurrence of automobile or haul truck accidents and would be considered a **potentially significant direct** impact. **No indirect** impacts would occur. ***[Similar]***

Mitigation Measure: Implement Mitigation Measure 3B.15-1a.

Implementation of Mitigation Measure 3B.15.1a would ensure that construction-related hazards on local roadways would be reduced to a **less-than-significant** level by ensuring proper notification to drivers of construction zones. All roadway-related improvements (e.g., pipelines) would be located sub-surface and would not contribute to any significant roadway design hazards and no long-term impacts are anticipated.

IMPACT 3B.15-4 Possible Inadequate Emergency Vehicle Access. *Construction of the Off-site Water Facilities could result in disruptions to emergency access.*

NCP, PA, 1, 1A, 2, 2A, 2B, 3, 3A, 4, and 4A

Access to driveways and to cross-streets along the pipeline construction route would be temporarily blocked due to trenching and paving operations during construction of the Off-site Water Facilities. This could be disruptive, particularly with respect to agricultural operations as well as for movement of emergency vehicles through the Off-site Water Facilities Study Area. Vehicle access would be restored at the end of each work day through the use of steel trench plates or trench backfilling. Emergency vehicle access to the residences in the immediate vicinity of the Off-site Water Facilities would have a minimal potential for being impeded for a few minutes. Construction-related vehicles would yield to emergency vehicles, as necessary. Based on these considerations, the **direct** impact is considered **less than significant**. **No indirect** impacts would result. ***[Similar]***

Mitigation Measure: No mitigation measures are required.

3B.15.4 RESIDUAL SIGNIFICANT IMPACTS

Through the implementation of Mitigation Measure 3B.15-1, potentially significant traffic impacts resulting from the construction of the Off-site Water Facility Alternatives would be reduced to a less-than-significant level through proper construction sequencing, maintenance of two-way traffic, where possible, during construction, and measures to avoid the creation of traffic hazards. Based on these findings, the Off-site Water Facility Alternatives would not result in any residual significant and unavoidable impacts to traffic.

3A.16 UTILITIES AND SERVICE SYSTEMS - LAND

3A.16.1 AFFECTED ENVIRONMENT

WASTEWATER COLLECTION AND TREATMENT

The SPA is presently not served by any municipal wastewater collection and treatment systems. Approximately 3,313 acres of the SPA west of Empire Ranch Road is within the Sacramento Regional County Sanitation District (SRCSD) and the remaining 189 acres east of Empire Ranch Road is within both the SRCSD and El Dorado Irrigation District (EID) service areas. Existing and proposed on- and off-site facilities are shown in Exhibit 2-9 in Chapter 2, "Alternatives."

Sacramento Regional County Sanitation District

Wastewater Collection

Sanitary-sewer service for approximately 3,313 acres of the SPA would be provided by SRCSD, and SRCSD would provide off-site interceptor conveyance and sanitary sewer treatment and disposal for this portion of the SPA. SRCSD is responsible for collection by interceptors (sanitary sewers that are designed to carry flows in excess of 10 million gallons per day [mgd]) and for wastewater treatment in Sacramento County. This district owns, operates, and is responsible for the public collection, trunk, and interceptor sewer systems throughout Sacramento County as well as the Sacramento Regional Wastewater Treatment Plant (SRWTP) located south of the community of Freeport.

The Proposed Project Alternative would construct an off-site sewer force main to connect with SRCSD's Folsom East Interceptor. Sacramento County evaluated the environmental impacts of constructing trunk and interceptor sewers that would serve most of the Sacramento region (including the SPA) at a programmatic level in the *Sacramento Regional County Sanitation District Interceptor Master Plan 2000, Final Program Environmental Impact Report* (State Clearinghouse [SCH] No. 2001112085) (SRCSD 2003a). This EIR was certified and the master plan approved in March 2003.

The purpose of the *SRCSD Interceptor System Master Plan 2000* (SRCSD 2003b) is to identify near- and long-term improvements needed for the regional wastewater conveyance system. The master plan describes the regional interceptor projects, along with their timing and costs, so that existing and future deficiencies in the regional system can be more accurately identified and predicted and strategic approaches to remedying these deficiencies can be developed. The plan uses new information regarding population growth, wastewater flow generation, and actual system responses to wet weather. The SRCSD's Master Plan 2000 includes the Folsom East Interceptor, which was constructed to convey project-related wastewater flows.

The wastewater flows generated by the Proposed Project Alternative, including the 189-acrea portion of the SPA that would be served by EID, have been planned for in the SRCSD Master Plan 2000. The master plan estimates that buildout of the SPA would generate an average dry-weather flow of 6.82 mgd a peak wet-weather flow of 14.48 mgd (SRCSD 2003b:Table 3-1). The master plan assumes buildout of the SPA would be beyond the plan's 2020 planning horizon; however, the wastewater flows generated by the project at buildout were planned for and evaluated in the master plan. Because 189 acres of the SPA would be served by EID, project-related wastewater flows would be less than those identified in the SRCSD Master Plan 2000.

The Proposed Project Alternative would connect to an existing 24-inch force main located within Iron Point Road north of U.S. 50 downstream of the existing Folsom East 3B Pump Station. Exhibit 2-9 illustrates the location of this off-site connection. The existing 24-inch force main is currently a dry pipeline and was constructed as part of the Folsom East Interceptor for future use by the Proposed Project Alternative. The existing 24-inch force main runs parallel to the Folsom East 3B 18-inch force main, and these force mains travel west in Iron Point Road to

the intersection of Iron Point Road and McAdoo Road where they connect to the Folsom East Interceptor Section 3A 36-inch gravity sewer pipe.

Wastewater Treatment

Wastewater flows collected from the SRCSD interceptors are ultimately transported into the SRWTP. The SRWTP receives and treats an average of 141 mgd (as of 2008) and has a permitted dry-weather flow design capacity of 181 mgd. In 2000, flows were approximately 155 mgd and were projected to increase and surpass the 181 mgd capacity by 2007. However, flows to the SRWTP have since decreased and there is currently 40 mgd of available capacity within the 181 mgd.

Wastewater conveyed to the SRWTP is treated to a secondary level and is ultimately discharged into the Sacramento River. The SRWTP has a National Pollutant Discharge Elimination System (NPDES) permit issued by the Central Valley Regional Water Quality Control Board (RWQCB) for discharge of up to 181 mgd of treated effluent into the Sacramento River. SCRSD certified the *Sacramento Regional Wastewater Treatment Plant 2020 Master Plan Final Environmental Impact Report* (SRCSD 2004) (SCH No. 2002052004) in June 2004. The adequacy of the EIR has been challenged, and the case is pending review in the 3rd District Court of Appeal. The Court of Appeal could overturn or uphold the Superior Court's determination in whole or in part. The Court of Appeal has not yet issued its own ruling, and it would be speculative to predict the outcome. However, a decision by the court is expected in 2010 (*see Contra Costa Water District v. Sacramento County Regional Sanitation District,* appellate case number C058460, available at http://appellatecases.courtinfo.ca.gov/search/case/mainCaseScreen.cfm?dist=3&doc_id=1202308&doc_no=C058460&search=number&start=1&query_caseNumber=C058460). Significant impacts were identified in the EIR, and a summary of the environmental impacts have been incorporated by reference and are summarized in this section as they relate to the contributions to the potential need for expansion of the SRWTP by the project.

The *Sacramento Regional Wastewater Treatment Plant 2020 Master Plan* (2001) provides for the expansion of the SRWTP to 218 mgd based on growth rates expected to be achieved in the Sacramento County region, and provides a phased program of recommended wastewater treatment facilities and management programs to accommodate planned growth and to meet existing and anticipated regulatory requirements through the year 2020. The master plan addresses both public health and environmental protection issues while ensuring reliable service at affordable rates for SRCSD customers. The key goals of the master plan are to provide sufficient capacity to meet growth projections and an orderly expansion of SRWTP facilities, comply with applicable water quality standards, and provide for the most cost-effective facilities and programs from a watershed perspective.

As part of the 2005 permit renewal process, the SRWTP applied to the Central Valley RWQCB for a NPDES permit to accommodate these additional discharges into the Sacramento River. In June 2010 the SRCSD removed its formal request to the Central Valley RWQCB for an increase in permitted wastewater discharge capacity. Flows to the SRWTP have decreased from water conservation efforts over the last 10 years and it is anticipated that State legislation passed in 2009, which mandates further water conservation efforts, could substantially reduce the amount of wastewater in the future. In addition, the SRCSD has prioritized its goals to increase water recycling in the region as an element to support the comprehensive effort to promote water supply reliability and Delta sustainability. Therefore, the SRCSD has determined the SRWTP can provide capacity to future development beyond what was originally anticipated. (SRCSD 2010).

El Dorado Irrigation District

Wastewater Collection

An approximately 189 acre portion of the SPA east of Empire Ranch Road is within the EID service area. Within the vicinity of the SPA there are existing EID sewer mains in El Dorado Hills. These sewer mains include: a 6-inch sewer main at Winterfield Court, a 6-inch sewer main at the intersection of Stonebriar Drive and Prima Way, and a 6-inch sewer main at Ranch Bluff Way south of White Rock Road. The sewer flows from this community

are conveyed to an existing pump station at the intersection of White Rock Drive and Winterfield Drive (Exhibit 2-7 in Chapter 2, "Alternatives."). Wastewater flows collected from EID's sewer system are ultimately transported into the El Dorado Hills Wastewater Treatment Plant (WWTP).

Wastewater Treatment

EID adopted its *Wastewater Master Plan Update* in November 2001 (HDR Engineering 2001). The master plan update includes estimates of existing and projected wastewater flows from the area served by EID's sewer collection system, projects wastewater treatment needs for the EID service area through 2025, and identifies system expansions and upgrades needed to meet projected increases in wastewater flows. Project-related wastewater flows were not evaluated in the EID Master Plan Update.

Currently, the El Dorado Hills WWTP's design capacity is 3.0 mgd average dry-weather flow and 7.6 mgd peak wet-weather flow. As of 2009, the average dry-weather flow is approximately 2.86 mgd and peak wet-weather flow is 8.04 mgd (Central Valley RWQCB 2007; Caulfield, pers. comm. 2009). Expansion of the WWTP is required to provide wastewater treatment capacity for land uses in El Dorado Hills as identified by the El Dorado County General Plan (2003), to meet anticipated regulatory requirements for water quality, and to help meet recycled water demands (EID 2007:2).

The environmental impacts of the expansion and operation of the El Dorado Hills WWTP were analyzed in an initial study/mitigated negative declaration (IS/MND) (SCH No. 2006082058), which was adopted by EID in June 2007 (EID 2007). Improvements to the WWTP identified and analyzed in the IS/MND include: new headworks, pumping stations, tertiary filters, ultraviolet disinfection, odor control, an administrative building, storage pond lining, and chemical feed system improvements. The capacity of the treatment plant would be expanded to 5.4 mgd in two phases. The first phase of the treatment plant expansion to 4.0 mgd is expected to be completed in 2010, with full buildout to 5.4 mgd by 2025 (Caulfield, pers. comm. 2009).

Treated effluent from the El Dorado Hills WWTP is discharged to Carson Creek under standards established by the Central Valley RWQCB. A portion of the effluent from the El Dorado Hills WWTP is pumped into the 1.0-million-gallon "960" storage tank south of the treatment plant. Flow are pumped from the 960 storage tank to the Silva Valley booster pump station, which pumps a maximum of 3,900 gpm, and the 2.0-million gallon "Village C" storage tank and booster pump station, which pumps a maximum of 2,600 gpm (HDR Engineering 2002:2-4). These booster pump stations provide reclaimed water for urban irrigation in the Serrano development and two golf courses. During the summer, there is sufficient recycled water demand that no flow is discharged to Carson Creek (HDR Engineering 2001:1-1.) See Section 3A.18, "Water Supply," for additional information on reclaimed water supply and uses.

SOLID WASTE

The City of Folsom Solid Waste Division provides solid waste, recycling, and hazardous materials collection services to the city. Waste is transported to the Kiefer Landfill, near the intersection of Grant Line Road and Kiefer Boulevard.

Sacramento County owns and operates the Kiefer Landfill, and the landfill is the primary solid waste disposal facility in the County. Kiefer Landfill is a total of 1,084 acres in size, with a permitted disposal area of 660 acres. Kiefer Landfill is classified as a Class III municipal solid waste landfill facility and is permitted to accept general residential, commercial, and industrial refuse for disposal, including municipal solid waste, construction and demolition debris, green materials, agricultural debris, and other nonhazardous designated debris. Kiefer Landfill produces enough renewable energy methane gas to power 9,000 homes (Sacramento County 2009a:4-2).

The landfill is permitted to accept a maximum of 10,800 tons per day (tpd) of solid waste; however, the average intake is only approximately 6,000 tpd. The Kiefer Landfill receives over 700,000 tons of waste per year

(Sacramento County 2009a:4-2). The site currently has a permitted capacity of approximately 117 million cubic yards and a remaining capacity of 113 million cubic yards. Currently, the landfill is operating below permitted capacity, and the closure date of the Kiefer Landfill is anticipated to be approximately 2064. (California Integrated Waste Management Board [CIWMB] 2008a.)

The CIWMB provides an average per-capita solid-waste disposal rate for Sacramento County of 0.36 ton per resident per year (CIWMB 2008b). Business waste disposal rates calculated by CIWMB range from 0.3 ton per year for general-merchandise stores to 3.1 tons per year for restaurants (CIWMB 2008c).

Construction of the two roadway connections into El Dorado Hills would generate temporary, short-term construction-related debris and solid waste. In El Dorado County, solid waste is disposed of at the Lockwood Regional Landfill located in Sparks, Nevada. The Lockwood Landfill is a Class I landfill that currently accepts an average of 7,700 tpd of solid waste. The existing permit does not restrict the maximum daily and yearly tonnage that may be received by the landfill, and the facility has a remaining capacity of 32.5 million tons. The landfill currently operates on 1,100-acre site, and the closure year of the landfill at 2035. (City of Sacramento 2009a:6.11-95, El Dorado County 2003:5.6-20).

Recycling Facilities

The California Integrated Waste Management Act (CIWMA) of 1989, also commonly known as Assembly Bill (AB) 939, requires local agencies to implement source reduction, recycling, and composting (see discussion under "Regulatory Framework" below). The Sacramento County Integrated Waste Management Plan, adopted in March 1996, consists of a siting element, summary plan, source reduction and recycling, household hazardous wastes, and non-disposal facility elements (Sacramento County 2009a:4-13). The countywide Integrated Waste Management Plan requires recycling programs that are expected to result in a 50% diversion away from landfills, thereby extending the life of landfills. According the 2006 Regional Waste Management Authority Annual Report, Sacramento County showed that 56% of the solid waste generated in the county was diverted from landfills through recycling, composting, and other waste diversion methods (CIWMB 2008d).

Sacramento County requires all contractors to comply with the Construction and Demolition Ordinance (Title 6, Chapter 6.20), which applies to all new commercial, office, industrial, multifamily residential, and public/quasi-public building permits over $250,000 in value (Sacramento County 2009b). The City of Folsom also requires all contractors to comply with the Construction and Demolition Recycling Ordinance (Title 8, Chapter 8.30), which requires construction and demolition contractors for projects with a valuation equal to or in excess of $100,000 to reduce all project waste by weight from entering landfill facilities by 50% through recycling (City of Folsom 2006). Covered projects must recycle five different types of debris and materials: scrap metal; inert materials (concrete, asphalt paving, bricks); corrugated cardboard; wood pallets; and clean wood waste. Both the County and City require contractors to document types of building materials and estimated quantities on a "Waste Management Plan" before obtaining building permits; within 30 days of project completion contractors must complete the "Waste Management Plan" to document the actual quantity of construction or demolition waste generated and demonstrate the actual quantities recycled, salvaged or reused, and/or disposed.

Similarly, El Dorado County requires all contractors to comply with the County's Construction and Demolition Debris Recycling Ordinance (Title 8, Chapter 8.43), which requires projects in excess of 5,000 square feet to reduce all project waste by weight from entering landfill facilities by 50% through recycling. Under this ordinance, contractors are required to submit a "Debris Recycling Acknowledgment" for review and approval at the time of submitting an application for a building permit. Within 60 days after completion and/or occupancy contractors must submit a "Debris Recycling Report" to document the actual quantity of construction or demolition wastes generated and demonstrate the actual quantities recycled, salvaged or reused, and/or disposed. (El Dorado County 2009.)

ELECTRICAL SERVICE

Sacramento Municipal Utility District (SMUD) generates, transmits, and distributes electric power to a 900-square-mile territory in Sacramento County, including the City of Folsom, and a small portion of Placer County. SMUD serves a population of 589,599 customers (522,228 residential and 67,361 commercial) with 2,226 employees, 473 miles of transmission lines (110 kilovolts [kV] or more), and 9,784 miles of distribution lines (typically 12 kV) (SMUD 2007a, 2008a). In 2007, SMUD generated approximately 10,917 million kilowatt (kW) hours of electricity within its service area (California Energy Commission [CEC] 2008a).

SMUD received approval from CEC to build the first phase of the 500-megawatt (MW) Cosumnes Power Plant (CPP), which provides the utility with 1,000 MW of power to ensure SMUD's long-range plans to meet the growing power needs of Sacramento County. The gas-fired plant, which came on line in 2006, provides enough power to meet the annual needs of 450,000 single-family homes (SMUD 2006).

In addition to the CPP, SMUD has the Upper American River Project, which consists of 11 reservoirs and eight powerhouses that generate enough electricity to meet nearly 15% of SMUD's customer demand. The Upper American River Project can provide approximately 1.8 million MW of electricity during a normal water year, which is enough energy to power about 180,000 homes (SMUD 2009).

SMUD has long-term contracts with other generators to provide an additional 1,189 MW of electricity for distribution per day. Throughout the year, SMUD buys and sells energy and capacity on a short-term basis to meet load requirements and reduce costs. In July 2006, SMUD experienced a record peak electricity daily demand of 3,299 MW (SMUD 2008b). Table 3A.16-1 shows SMUD's historic electrical consumption and forecasts of future consumption.

Table 3A.16-1
SMUD Service Area Electrical Consumption and Forecast

Year	Consumption (Gigawatt Hours)[1]
1990	8,358
2000	9,491
2005	10,523
2008	11,174
2013	12,053
2016	12,555

Note:
[1] Gigawatt equals one billion watts.
Source: CEC 2007:148

An electrical transmission corridor traverses the western portion of the SPA between U.S. Highway 50 (U.S. 50) and White Rock Road. The corridor contains one 115-kV and one 230-kV Pacific Gas & Electric Company (PG&E) double-circuit transmission lines that extend south from PG&E's Gold Hill Substation. The corridor also contains a SMUD 230-kV double-circuit transmission line that originates from SMUD's Lake Substation. The transmission line travels south from the substation and through the SPA (Capitol Utility Specialists 2009:2). Listed below are the other electrical transmission lines in the vicinity of the SPA include (Capitol Utility Specialists 2009:2 and 3).

- A 69-kV overhead single-circuit transmission line located in the south-central portion of the SPA. This transmission line travels south through the SPA for approximately 2,100 feet then turns west onto Prairie City Road.

- A 69-kV single-circuit transmission line that extends south along Prairie City Road until it reaches the point where the road curves west. The transmission line continues south approximately 7,700 feet along the west side of Prairie City Road to White Rock Road.

- A 69-kV single-circuit transmission line that extends south from U.S. 50 on the east side of Placerville Road where it terminates just within the SPA.

- A 12-kV overhead transmission line that extends north from White Rock Road along the east side of Placerville Road where it terminates with service facilities on U.S. 50.

Energy Conservation

SMUD has created two separate programs to grow renewable energy supplies for its customers: a green pricing program called Greenergy and a Renewables Portfolio Standard (RPS) program. Accounting for SMUD's renewable energy supply is done separately for these two programs and aggregated as SMUD's total, non-large hydro-renewable energy supply.

SMUD has had the green pricing program called "Greenergy" since 1997. Greenergy allows customer choice in selecting renewable energy supply for 100% or 50% of their electricity based on a simple monthly fee of $6.00 or $3.00, respectively. Commercial Greenergy customers pay $0.1 per kilowatt-hour (kWh) for 100% renewables and $0.5 per kWh for 50% renewable energy. In 2006, there were about 36,000 participating customers in the Greenergy program, of which approximately 34,000 were residential customers. (SMUD 2008b.)

SMUD's RPS program was approved by SMUD's elected board one year before the state RPS program was approved by the legislature and governor. To meet its annual renewables goals, SMUD both contracts for renewable electricity from independent power producers and builds and owns renewable energy power plants. SMUD has renewable energy supply goals of 23% for 2011 (20% RPS + 3% Greenergy in 2011). The final supply numbers compiled for 2006 show that SMUD provided about 13% of retail sales of eligible, non-large hydro-renewable electricity supply. (SMUD 2007b:2.)

SMUD has supported several new renewables projects that have begun providing electricity to the grid since 2002. The SMUD-owned Solano wind project installed wind turbines generating 39 MW in 2002, and an additional 63 MW of wind turbines were installed in 2007. This wind project is expected to have turbines generating over 200 combined megawatts installed by 2011. SMUD also recently signed a Power Purchase Agreement (PPA) contract for the second phase of the Kiefer Landfill gas-to-electricity project, which is online now and providing an additional 5.7 MW. SMUD also signed a PPA several years ago for a California wind project that came online in phases from 2003 to 2007, and it now provides a total of 75 MW. (SMUD 2007b:3.)

NATURAL GAS SERVICE

Natural gas service in Folsom is provided by PG&E through portions of PG&E's 46,000 miles of natural gas distribution pipelines. In 2007, PG&E delivered approximately 4,562 million therms (MM therms) of natural gas throughout its service area (CEC 2008b). Table 3A.16-2 shows PG&E's historic natural gas consumption and forecasts of future consumption.

Whenever possible, PG&E adds capacity in an existing easement either by replacing smaller mains with larger mains, by constructing additional mains parallel to the existing facilities, or by increasing the operating pressure of existing mains (Sacramento County 2007:69). A 10-inch natural gas distribution feeder main is located in the east side of Placerville Road. This main extends south and then east along the south side of White Rock Road and into El Dorado County (Capitol Utility Specialists 2009:4).

Table 3A.16-2 PG&E Service Area Natural Gas Consumption and Forecast	
Year	Consumption (MM Therms)
1990	5,275
2000	5,291
2005	4,724
2008	4,895
2018	5,144
Source: CEC 2007:204	

In addition, the following natural gas transmission mains are located in the vicinity of the SPA (Capitol Utility Specialists 2009:6):

- a 6-inch transmission main on the west side of Prairie City Road approximately 915 feet north of U.S. 50,
- a 4-inch transmission main on Oak Avenue approximately 1,250 feet north of U.S. 50,
- a 6-inch transmission main at the intersection of East Bidwell Street and Iron Point Road approximately 1,280 feet north of U.S. 50,
- an 8-inch transmission main on Placerville Road north of U.S. 50, and
- a 6-inch transmission main at Stonebriar Road and White Rock Road.

PG&E has several natural gas regulator stations that could serve the SPA. Regulator stations in the vicinity of the SPA are located on East Bidwell Street at Oak Avenue, on Blue Ravine Road at Riley Street, and at Stonebriar Drive and White Rock Road in El Dorado County (Capitol Utility Specialists 2009:6).

TELECOMMUNICATIONS

AT&T Inc. (AT&T) would be provided telecommunications service to the SPA. Currently, there are no existing telephone lines in the SPA. AT&T has existing underground telephone lines extending east from Prairie City Road along both side of White Rock Road. In addition, AT&T has existing overhead fiber optic cable that extends west from the El Dorado County line and parallels U.S. 50 on the south side where it connects to SMUD's 12kV overhead transmission line. (Capitol Utility Specialists 2009.)

CABLE TELEVISION AND COMMUNICATIONS

Comcast would provide cable television and communications service to the SPA. Comcast serves the city with a combination of underground and overhead fiber-optic cable and copper coaxial cable. Additional improvements or relocations of hub sites are generally made as the need arises to meet customer demand.

Currently, there are no existing cable television and communications facilities in the SPA. In the vicinity of the SPA, Comcast has existing facilities on Prairie City Road and along Iron Point Road north of U.S. 50 (Capitol Utility Specialists 2009:8).

3A.16.2 REGULATORY FRAMEWORK

FEDERAL PLANS, POLICIES, REGULATIONS, AND LAWS

There are no Federal plans, policies, regulations, or laws related to utilities and service systems that apply to the Proposed Project or alternatives under consideration.

STATE PLANS, POLICIES, REGULATIONS, AND LAWS

California Integrated Waste Management Act

To minimize the amount of solid waste that must be disposed of by transformation and land disposal, the California Legislature passed the CIWMA of 1989 (AB 939), effective January 1990 (CIWMB 2007). According to the CIWMA, all cities and counties were required to divert 25% of all solid waste from landfill facilities by January 1, 1995, and 50% by January 1, 2000. Each city is required to develop solid waste plans demonstrating integration of the CIWMA plan with the county plan. The plans must promote (in order of priority) source reduction, recycling and composting, and environmentally safe transformation and land disposal.

California Public Utilities Commission Decision 95-08-038

The California Public Utilities Commission (CPUC) Decision 95-08-038 contains the rules for the planning and construction of new transmission facilities, distribution facilities, and substations. The decision requires permits for the construction of certain power line facilities or substations if the voltages would exceed 50 kV or if the substation would require the acquisition of land or an increase in voltage rating above 50 kV. Distribution lines and substations with voltages less than 50 kV do not need to comply with this decision; however, the utility must obtain any nondiscretionary local permits required for the construction and operation of these projects. CEQA compliance is required for construction of facilities constructed in accordance with the decision.

California Building Energy Efficiency Standards

The project would be required to comply with changes to Title 24 of the California Code of Regulations regarding energy efficiency that became effective on October 1, 2005. These new energy efficiency standards were developed in response to the state's energy crisis as well as AB 970 (Chapter 329, Statutes of 2000), the California Energy and Reliability Act of 2000. The goals of the recent changes to Title 24 are to improve the energy efficiency of residential and nonresidential buildings, minimize impacts during peak energy-usage periods, and reduce impacts on overall state energy needs.

Implementation of these standards is expected to reduce the growth in electricity use by 478 gigawatt-hours per year (GWh/y) and reduce the growth in natural gas use by 8.8 million therms per year. The savings attributable to new nonresidential buildings are 163.2 GWh/y of electricity savings and are expected to reduce the growth in electricity use by 478 GWh/y and reduce the growth in natural gas use by 8.8 MM therms per year. The savings attributable to new nonresidential buildings are 163.2 GWh/y of electricity savings and 0.5 MM therms. Additional savings result from the application of the standards on building alterations. In particular, requirements for cool roofs, lighting, and air distribution ducts are expected to save about 175 GWh/y of electricity.

In addition, the 2008 California Building Code (Part 11 of Title 24) standards were adopted on July 1, 2008 and became effective on August 1, 2009. This code was developed to enhance the design and construction of buildings and sustainable construction practices through planning and design, energy efficiency, water efficiency and conservation, material conservation and resource efficiency, and environmental air quality. It is the intent of this code to encourage green buildings to achieve to achieve more than a 15% reduction in energy usage when compared to existing standards, to reduce indoor potable water demand by 20%, to reduce landscape water usage by 50%, and to reduce construction waste by 50%.

REGIONAL AND LOCAL PLANS, POLICIES, REGULATIONS, AND LAWS

Sacramento County General Plan

There are no goals and policies of the Sacramento County General Plan (1993) that are applicable to the Proposed Project or alternatives under consideration.

El Dorado County General Plan

There are no goals and policies of the El Dorado County General Plan (2004) that are applicable to the Proposed Project or alternatives under consideration.

City of Folsom General Plan

The following goals and policies of the City of Folsom General Plan (1988) are applicable to the Proposed Project and the other four action alternatives. There are no City of Folsom goals and policies that would apply to the No Project Alternative.

Housing Element

GOAL 22: To promote energy conservation.

- **Policy 22.2:** Include energy conservation guidelines as part of the development standards for the specific plan area.

Public Facilities Element

GOAL 40: To set targets for ultimate build-out of the City, to plan for the provision of public facilities and services to meet this level of development, and to phase development according to the capacity of public facilities and services to meet those targets.

- **Policy 40.1:** No permit for construction shall be issued for any new development not served by existing municipal facilities until the following conditions have been met:
    - The applicant can provide for the installation and/or financing (through fees or other means) of needed public facilities.
    - The project is included in the area covered by an existing facilities plan approved by the City.
    - The project can be served by on-site or private facilities meeting City and County health and safety requirements.
- **Policy 40.2:** The City shall require the preparation of a facilities plan for an identified area when:
    - Development of an area necessitates the provision, extension, and/or expansion of municipal services and facilities which are not customarily constructed by a developer, or
    - There is a need for services or facilities not otherwise funded by regular City fees, or
    - The construction of the necessary services and facilities cannot be logically or economically provided by one landowner/development in the normal sequence of orderly development.
- **Policy 40.3:** An area facilities plan shall include, but not limited to the following:

- Description of the plan area, the basis for the selection of the proposed boundaries, and the development potential of the area which is based on a comprehensive land use map.

- A statement of the plan's consistency with the Folsom General plan and the City's Urban Development Policy.

- Identification of the nature and extent of facilities necessary to serve the area and a schedule of estimated time within which facilities must be constructed.

- Engineer's estimate of the total cost of such improvements (including plan preparation).

- A plan for the equitable apportionment of costs among benefited properties and adjustments thereof based on the time such costs are paid.

- The nature of the obligation of each land-owner or developer.

- Discussion of the options available to finance the improvements including, but not limited to, construction by developers.

- Provisions for amendments to the plan which may result from changes in the plan area, development patterns, etc.

- Provisions to refund or reimburse landowners who construct facilities with capacity beyond the ultimate need of their developments.

- A statement which recognizes that the financial commitments required pursuant to such plans are not in lieu of other municipal service and facilities fees. The financial commitments of landowners/developers shall be taken into account by the City in determining the extent of the imposition of such other municipal service and facilities fees.

- A statement which recognizes that the area facilities plan is not intended to be responsible for the provision of all possible public facilities that will be needed in the future and that there are or may be additional costs/fees established by the City and other jurisdictions (such a school district) that may apply to the area. However, the plan must address the need for public facilities which may reasonably be assumed to be necessary during buildout of the area.

- Provisions for administration of the area plan and the collection and distribution of funds.

► **Policy 40.4:** All new development projects shall be planned for an urban level of services:

- Sanitary sewer lines of appropriate size to accommodate the project and that will tie into the City's main lines.

3A.16.3 Environmental Consequences and Mitigation Measures

Thresholds of Significance

The thresholds for determining the significance of impacts for this analysis are based on the environmental checklist in Appendix G, and based on Appendix F as related to energy, of the State CEQA Guidelines. These thresholds also encompass the factors taken into account under NEPA to determine the significance of an action in terms of its context and the intensity of its impacts. The Proposed Project or alternatives under consideration were determined to result in a significant impact related to utilities and service systems if they would do any of the following:

- exceed wastewater treatment requirements of the applicable RWQCB;
- require or result in the construction of new wastewater treatment facilities or expansion of existing facilities, the construction of which could cause significant environmental effects;
- result in a determination by the wastewater treatment provider that serves or may serve the project that it has inadequate capacity to serve the project's projected demand in addition to the provider's existing commitments;
- generate solid waste beyond the capacity of existing landfills;
- violate Federal, state, or local statutes and regulations related to solid waste; or
- result in inefficient, wasteful, and unnecessary consumption of energy.

ANALYSIS METHODOLOGY

Impacts on utilities and service systems that would result from implementation of the Proposed Project and alternatives under consideration were identified by comparing existing service capacity and facilities against future demand associated with project implementation. Evaluation of potential utility and service systems impacts was based on a review of the following documents pertaining to the SPA and surrounding area:

- *Sacramento County General Plan* (Sacramento County 1993),
- *Sacramento County General Plan Background to the 1993 General Plan and 2007 General Plan Update* (Sacramento County 2007),
- *Sacramento County General Plan Update DEIR* (Sacramento County 2009),
- *City of Folsom General Plan* (City of Folsom 1988),
- *Wastewater Infrastructure Plan for the Folsom Specific Plan Area* (MacKay & Somps 2008a, provided in Appendix K1),
- *Addendum No. 1. Wastewater Infrastructure Plan for the Folsom Specific Plan Area* (MacKay & Somps 2008b, provided in Appendix K2),
- *Wastewater Master Plan Update for El Dorado Irrigation District* (HDR Engineering 2001),
- *Sacramento Regional County Sanitation District Interceptor Master Plan 2000, Final Program Environmental Impact Report* (SCH No. 2001112085) (SRCSD 2003a),
- *Sacramento Regional County Sanitation District Interceptor System Master Plan 2000* (SRCSD 2003b),
- *Sacramento Regional Wastewater Treatment Plant 2020 Master Plan Final Environmental Impact Report* (SCH No. 2002052004) (SRCSD 2004),
- *Sacramento Regional Wastewater Treatment Plant 2020 Master Plan* (SRCSD 2001), and
- *Folsom Plan Area Technical Dry Utilities Study* (Capitol Utility Specialists 2009, provided in Appendix G11).

Additional information was obtained through consultation with appropriate agencies, including SRCSD, EID, SMUD, PG&E, and field review of the SPA and surroundings.

Where possible, a quantitative comparison was used to determine impacts of the project on future demands. Tables 3A.16-3, 3A.16-4, and 3A.16-5 summarize wastewater generation, solid waste generation, and electrical and natural gas service demands, respectively.

Table 3A.16-3
Folsom South of U.S. 50 Specific Plan Wastewater Generation Rates

Alternative	Wastewater Generated in the SRCSD Service Area		Wastewater Generated in the EID Service Area	
	Average Dry-Weather Flow (mgd)	Peak Wet-Weather Flow (mgd)	Average Dry-Weather Flow (mgd)	Peak Wet-Weather Flow (mgd)
Proposed Project	5.58	11.99	0.28	0.70
Resource Impact Minimization	4.24	9.38	0.22	0.55
Centralized Development	4.59	9.96	0.05	0.14
Reduced Hillside Development	5.66	11.96	0.23	0.59
No USACE Permit	3.83	8.58	0.31	0.78

Notes: mgd = million gallons per day
Development of residences under the No Project Alternative would use on-site septic systems for wastewater treatment.
Source: MacKay & Somps 2008b; Zoller, pers. comm. 2009

Table 3A.16-4
Folsom South of U.S. 50 Specific Plan Solid Waste Generation Rates

Alternative	Residential Waste (tpd) [1]	Business Waste (tpd) [2]	Total (tpd)
No Project	0.1	--	0.1
Proposed Project	24.0	65.1	89.1
Resource Impact Minimization	19.3	48.0	67.3
Centralized Development	20.4	83.1	103.5
Reduced Hillside Development	24.7	86.2	110.9
No USACE Permit	15.6	64.2	79.8

Notes: tpd = tons per day
[1] Based on CIWMB's average per-capita solid-waste disposal rate for Sacramento County of 0.36 ton per resident per year.
[2] The business waste–disposal rate calculated by CIWMB for project development was based on an average of 1.8 tons per year per employee.
Source: Data compiled by AECOM in 2010

IMPACT ANALYSIS

Impacts that would occur under each alternative development scenario are identified as follows: NP (No Project), NCP (No USACE Permit), PP (Proposed Project/Action), RIM (Resource Impact Minimization), CD (Centralized Development), and RHD (Reduced Hillside Development). The impacts for each alternative are compared relative to the PP at the end of each impact conclusion (i.e., similar, greater, lesser).

Table 3A.16-5 Folsom South of U.S. 50 Specific Plan Electrical and Natural Gas Demands			
Alternative	Electrical Demand		Natural Gas Demand [1]
	Average Demand (MVA)	Peak Demand (MVA)	Peak Demand (MCFH)
No Project	0.1	0.2	2.2
Proposed Project	39.7	87.3	818.3
Resource Impact Minimization	34.5	75.9	694.2
Centralized Development	45.1	97.1	837.7
Reduced Hillside Development	52.0	111.5	978.6
No USACE Permit	35.7	78.0	655.9

Notes: MVA = megavolt amperes, MCFH = thousand cubic feet per hour

[1] No average natural gas demand was provided for the Proposed Project Alternative.

Source: Capitol Utility Specialists 2009

IMPACT 3A.16-1 Increased Demand for On-Site Wastewater Collection and Conveyance Facilities and the Off-Site Force Main. *Project implementation would result in increased generation of wastewater.*

On-Site Elements

NP

Under the No Project Alternative, development of up to 44 rural residences could occur under the existing Sacramento County agricultural zoning classification AG-80, and no off-site water facilities would be constructed. These residences would require the use of on-site septic systems. Therefore, the 44 individual rural residences that could be built under the No Project Alternative would not increase demand for municipal wastewater collection and conveyance facilities and there would be **no direct** or **indirect** impacts. See Section 3A.7, "Geology, Soils, Mineral, and Paleontological Resources - Land," for a discussion of the suitability of soils for use with septic systems. ***[Lesser]***

NCP, PP, RIM, CD, RHD

The SPA is presently not served by municipal wastewater collection and treatment systems, and therefore the project would require construction of on-site wastewater collection and conveyance facilities and an off-site force main.

The wastewater infrastructure plan prepared for the Proposed Project Alternative (MacKay & Somps 2008a) addressed the viability of providing sewer service to the SPA, identified on- and off-site facility needs and design, and evaluated designs for consistency with existing interceptor sewer master plans. The wastewater infrastructure plan presents options for the ultimate sewer conveyance facilities. However, detailed sewer master plans have not been completed. It is anticipated that additional work would be performed to define force mains, trunk, and major collectors; identify phased construction of facilities; and design tentative maps, including collector and lateral systems, to serve each lot. The following discussion provides an overview of the future facilities identified by the conceptual wastewater infrastructure plan (attached as Appendix K).

The sizing and design of the on-site sewer pipelines and pump stations and the off-site force main are based on Sacramento Area Sanitation District design standards. The on-site sanitary sewer system would consist of gravity pipelines and force mains ranging in size from 8 inches to 30 inches in diameter, and where possible, would be

installed at a depth of less than 20 feet. The proposed on-site sewer system and off-site force main would be sized to accommodate planned sewer flows.

Lands within the EID service area and a sub-shed east of Empire Ranch Road would be served by three pump stations. The East Sanitary Sewer Pump Station would be located at the northwest corner of White Rock Road and Empire Ranch Road, Pump Station 3 would be located at the eastern boundary of the SPA near Stonebriar Court, and Pump Station 4 would be located at the eastern boundary of the SPA near Winterfield Court. A combination of force mains and gravity sewers would convey wastewater south along the eastern boundary of the SPA to the East Sanitary Pump Station.

Sewer flows from the EID service area would be conveyed to an existing pump station at the intersection of White Rock Drive and Winterfield Drive and ultimately conveyed to the El Dorado Hills WWTP (see Impact 3A.16-5).

Sewer flows from the SRCSD service area would be conveyed to the Folsom South Pump Station north of Easton Valley Parkway and approximately 1,500 feet west of Oak Avenue. From the Folsom South Pump Station, the project would construct an off-site force main to convey flows to an existing SRCSD 24-inch force main located within Iron Point Road, north of U.S. 50, and downstream of the existing Folsom East 3B Pump Station (see Impact 3A.16-3).

Because the SPA is not served by a municipal wastewater collection system and sufficient on-site wastewater collection and conveyance infrastructure and the off-site force main necessary to serve the project have not been constructed, nor have final design plans and specifications been submitted, this is a **direct, potentially significant** impact. The **indirect** physical impacts of constructing these facilities are addressed throughout this EIR/EIS in connection with discussions of the impacts of overall site development. ***[Similar]***

> Mitigation Measure 3A.16-1: Submit Proof of Adequate On- and Off-Site Wastewater Conveyance Facilities and Implement On- and Off-Site Infrastructure Service Systems or Ensure That Adequate Financing Is Secured.
>
> Before the approval of the final map and issuance of building permits for all project phases, the project applicant(s) of all project phases shall submit proof to the City of Folsom that an adequate wastewater conveyance system either has been constructed or is ensured through payment of the City's facilities augmentation fee as described under the Folsom Municipal Code Title 3, Chapter 3.40, "Facilities Augmentation Fee – Folsom South Area Facilities Plan," or other sureties to the City's satisfaction. Both on-site wastewater conveyance infrastructure and off-site force main sufficient to provide adequate service to the project shall be in place for the amount of development identified in the tentative map before approval of the final map and issuance of building permits for all project phases, or their financing shall be ensured to the satisfaction of the City.
>
> **Implementation:** The project applicant(s) of all project phases.
>
> **Timing:** Before approval of final maps and issuance of building permits for any project phases.
>
> **Enforcement:** City of Folsom Community Development Department and City of Folsom Public Works Department.

Off-Site Elements

The sewer force main would provide the necessary infrastructure needed to provide wastewater service to the SPA, and construction of the off-site freeway interchange improvements, sewer force main, and the detention basin in Sacramento County, and the two roadway connections into El Dorado Hills would not involve construction of new housing or development of new businesses that would increase demand for wastewater

collection and conveyance facilities. Therefore, the off-site elements would have a **direct, less-than-significant** impact on the demand additional wastewater collection and conveyance facilities. The **indirect** physical impacts of constructing the sewer force main are addressed throughout this EIR/EIS in connection with discussions of the impacts of overall site development. ***[Similar]***

Mitigation Measure: No mitigation measures are required.

Implementation of Mitigation Measure 3A.16-1 would reduce significant impacts associated with increased demand for on-site wastewater collection facilities under the No USACE Permit, Proposed Project, Resource Impact Minimization, Centralized Development, and Reduced Hillside Development Alternatives to a **less-than-significant** level because adequate wastewater conveyance facilities would be documented or adequate financing would be secured before approval final maps and issuance of building permits.

IMPACT 3A.16-2 Increased Demand for SRCSD Off-Site Wastewater Collection and Conveyance Facilities. *The wastewater generated within the 3,313-acre SRCSD service area would require off-site collection facilities to the Folsom East Interceptor.*

On-Site Elements

NP

Under the No Project Alternative, development of up to 44 rural residences could occur under the existing Sacramento County agricultural zoning classification AG-80, and no off-site water facilities would be constructed. These residences would require the use of on-site septic systems. Therefore, the 44 individual rural residences that could be built under the No Project Alternative would not increase demand for municipal wastewater collection and conveyance facilities and there would be **no direct** or **indirect** impacts. See Section 3A.7, "Geology, Soils, Mineral, and Paleontological Resources - Land," for a discussion of the suitability of soils for use with septic systems. ***[Lesser]***

NCP, PP, RIM, CD, RHD

The wastewater generated within the 3,313-acre SRCSD service area would ultimately be conveyed to the Folsom South Pump Station north of Easton Valley Parkway and approximately 1,500 feet west of Oak Avenue (see Exhibit 2-6 in Chapter 2, "Alternatives"). From the Folsom South Pump Station, the project would construct an off-site force main to convey flows to an existing SRCSD 24-inch force main located within Iron Point Road north of U.S. 50 and downstream of the existing Folsom East 3B Pump Station. The existing 24-inch force main is currently a dry pipeline and was constructed as part of SRCSD's Folsom East Interceptor project for future use by the project. The existing 24-inch force main travels west in Iron Point Road to the intersection of Iron Point Road and McAdoo Road, where it connects to the 36-inch Folsom East Interceptor Section 3A gravity pipeline. Wastewater flow would ultimately be conveyed to the SRWTP.

SRCSD has designed and constructed the Folsom East Interceptor to serve the project, and this facility would be adequate to serve wastewater generated by the No USACE Permit, Proposed Project, Resource Impact Minimization, Centralized Development, and Reduced Hillside Development Alternatives; therefore, the increased demand for SRCSD off-site wastewater collection and conveyance facilities would be a **direct, less-than-significant** impact. **No indirect** impacts would occur. ***[Similar]***

Mitigation Measure: No mitigation measures are required.

Off-Site Elements

Construction of the off-site freeway interchange improvements, sewer force main, and the detention basin in Sacramento County, and the two roadway connections into El Dorado Hills would not involve construction of new housing or development of new businesses that would increase demand for off-site SRCSD wastewater collection and conveyance facilities. Therefore, the off-site elements would have **no direct** or **indirect** impacts.

Mitigation Measure: No mitigation measures are required.

IMPACT 3A.16-3 Increased Demand for SRWTP Wastewater Treatment Plant Facilities. *Project implementation would result in increased generation of wastewater. Collected wastewater flows from the 3,313-acre SRCSD portion of the SPA would ultimately be transported to the SRWTP for treatment and disposal.*

On-Site Elements

NP

Under the No Project Alternative, development of up to 44 rural residences could occur under the existing Sacramento County agricultural zoning classification AG-80, and no off-site water facilities would be constructed. These residences would require the use of on-site septic systems. Therefore, the 44 individual rural residences that could be built under the No Project Alternative would not increase demand for municipal wastewater treatment facilities and there would be **no direct** or **indirect** impacts. See Section 3A.7, "Geology, Soils, Mineral, and Paleontological Resources - Land," for a discussion of the suitability of soils for use with septic systems. ***[Lesser]***

NCP

As shown in Table 3A.16-3, implementation of the No USACE Permit Alternative would generate 3.83 mgd of average dry-weather flow, and 8.58 mgd peak wet-weather flow (MacKay & Somps 2008b; Zoller, pers. comm.). The No USACE Permit Alternative average-dry weather flow would be 1.75 mgd and peak-wet weather flow would be 3.41 mgd less than the Proposed Project Alternative.

The wastewater flows generated by the SPA, including the 189-acrea portion of the SPA that would be served by EID, have been planned for in the SRCSD Master Plan 2000. The master plan estimates that buildout of the SPA would generate an average dry-weather flow of 6.82 mgd a peak wet-weather flow of 14.48 mgd (SRCSD 2003b: Table 3-1). Because 189 acres of the SPA would be served by EID, the No USACE Permit Alternative average-dry weather flow would be 2.99 mgd and peak-wet weather flow would be 5.9 mgd less than those identified in the SRCSD Master Plan 2000.

Collected wastewater flows from the SPA would ultimately be transported to the SRWTP for treatment and disposal. The 2020 Master Plan provides for the expansion of the SRWTP to 218 mgd based on growth rates expected to be achieved in the Sacramento County region by 2020. This projected capacity specifically includes project-related wastewater flows through 2020. At the time the 2020 Master Plan EIR was prepared, it was assumed that flows would increase from 155 mgd and would surpass 181 mgd by 2007. However, flows to the SRWTP have consistently decreased between 2000 and 2008 from 155 mgd to 141 mgd. The reason for reduced flows is a result of water conservation efforts over the last 10 years. In addition, State legislation passed in 2009 and the SRCSD commitment to promote water supply reliability and Delta sustainability would substantially reduce the amount of wastewater generated in the future.

Note that this total does not represent a buildout population total for SRCSD; rather, it represents the amount of growth expected within SRCSD based on projections. The SRCSD has determined that growth within the district is less than what was projected in the 2020 master plan and the SRWTP can provide capacity to future development beyond what was originally anticipated. If substantial population growth or new development occurs before 2020, the SRCSD will reevaluate expansion needs and phase treatment plant expansion to provide for sufficient long-term capacity.

SCRSD prepared the *Sacramento Regional Wastewater Treatment Plant 2020 Master Plan Final Environmental Impact Report* (SRCSD 2004). As described above, the EIR was determined to be legally deficient by the Sacramento Superior Court and the judgment has been appealed. The legal effect of the pending appeal is to stay the Superior Court's determination of legal deficiency. Thus, this EIR/EIS summarizes below and incorporates by reference the significant impacts that were identified in the 2020 Master Plan EIR as they relate to the project.

Because there is a relationship between the project and the need for expansion the SRWTP, implementation of the No USACE Permit Alternative would contribute indirectly and incrementally to the related impacts (described above), most of which would be reduced to a less-than-significant level through implementation of mitigation measures. The only significant and unavoidable impact related to the treatment plant that was identified would be from short-term increases in NO_X during construction of SRWTP facilities. In addition to these impacts, there is a potential that new significant impacts to water quality could be identified if the EIR for the SRWTP is found inadequate and impacts are reanalyzed. It is too speculative to draw any such conclusion at this point since additional studies would be required to substantiate any new significant impacts.

Because the SRWTP is planned to accommodate growth in Sacramento regional area by 2020, development in the SPA that occurs by 2020 would be accommodated by planned SRWTP capacity. Over time, additional planning at the SRWTP would occur, and overall capacity would be assessed and additional capacity planned for and added. There is expected to be sufficient SRWTP capacity to accommodate project flows under the No USACE Permit Alternative through 2020. However, there would be no assurances that the SRWTP would have adequate capacity for new wastewater flows for project development occurring after 2020. Therefore, the potential lack of treatment capacity past 2020 at full project buildout is a **direct, potentially significant** impact. The No USACE Permit Alternative would also contribute to the need to expand the facility and therefore would contribute **indirectly** to the **significant and unavoidable** short-term impact related to air quality from expansion of the SRWTP identified in the 2020 Master Plan EIR. ***[Lesser]***

Mitigation Measure 3A.16-3: Demonstrate Adequate SRWTP Wastewater Treatment Capacity.

The project applicant(s) of all project phases shall demonstrate adequate capacity at the SRWTP for new wastewater flows generated by the project. This shall involve preparing a tentative map–level study and paying connection and capacity fees as identified by SRCSD. Approval of the final map and issuance of building permits for all project phases shall not be granted until the City verifies adequate SRWTP capacity is available for the amount of development identified in the tentative map.

Implementation: The project applicant(s) of all project phases.

Timing: Before approval of final maps and issuance of building permits for any project phases.

Enforcement: City of Folsom Community Development Department and City of Folsom Public Works Department.

PP

As shown in Table 3A.16-3, implementation of the Proposed Project Alternative would generate 5.58 mgd of average dry-weather flow and 11.99 mgd peak wet-weather flow within the SRCSD service area (MacKay & Somps 2008b).

The wastewater flows generated by the Proposed Project Alternative, including the 189-acrea portion of the SPA that would be served by EID, have been planned for in the SRCSD Master Plan 2000. The master plan estimates that buildout of the SPA would generate an average dry-weather flow of 6.82 mgd and a peak wet-weather flow of 14.48 mgd (SRCSD 2003b:Table 3-1). Because 189 acres of the SPA would be served by EID, the project-related average-dry weather flow would be 1.24 mgd and peak-wet weather flow would be 2.59 mgd less than those identified in the SRCSD Master Plan 2000.

Collected wastewater flows from the 3,313-acre SRCSD portion of the SPA would ultimately be transported to the SRWTP for treatment and disposal. The SRWTP receives and treats an average of 141 mgd (as of 2008) and has a permitted dry-weather flow design capacity of 181 mgd. Flows to the SRWTP would increase over time as the population in the SRCSD service area increases. At the time the 2020 Master Plan EIR was prepared, it was assumed that flows would increase from 155 mgd and would surpass 181 mgd by 2007. However, flows to the SRWTP have decreased between 2000 and 2008 from 155 mgd to 141 mgd.

As discussed above, SCRSD prepared the *Sacramento Regional Wastewater Treatment Plant 2020 Master Plan Final Environmental Impact Report* (SRCSD 2004), which was determined to be legally deficient by the Sacramento Superior Court. The judgment has been appealed, and a decision by the 3rd District Court of Appeals on the adequacy of the EIR is not expected until 2010. The Court of Appeal could overturn or uphold the Superior Court's determination in whole or in part. The legal effect of the pending appeal is to stay the Superior Court's determination of legal deficiency. Thus, this EIR/EIS summarizes below and incorporates by reference the significant impacts that were identified in the 2020 Master Plan EIR as they relate to this project.

The 2020 Master Plan, which was approved in 2004, provides for expansion of the SRWTP to 218 mgd based on growth rates expected to be achieved in the Sacramento County region by 2020. This projected capacity specifically includes project-related wastewater flows through 2020. Note that this total does not represent a buildout population total for SRCSD; rather, it represents the amount of growth expected within SRCSD based on projections. The SRCSD has determined that growth within the district is less than what was projected in the 2020 master plan and the SRWTP can provide capacity to future development beyond what was originally anticipated. If substantial population growth or new development occurs before 2020, the SRCSD will reevaluate expansion needs and phase treatment plant expansion to provide for sufficient long-term capacity.

Because there is a relationship between the project and the need for expansion of the SRWTP, implementation of the Proposed Project Alternative would contribute indirectly and incrementally to the related impacts. As described in the 2020 Master Plan EIR (which is incorporated by reference herein), construction and operation of the expanded SRWTP would result in several environmental impacts, and all but one impact would be reduced to a less-than-significant level through implementation of mitigation measures (including impacts on water quality, hydrology, fisheries, traffic, and noise). The only significant and unavoidable impact related to the treatment plant that was identified would be from short-term increases in nitrogen oxide (NO_X) during construction of SRWTP facilities.

In addition to these impacts, there is a potential that new significant impacts to water quality could be identified if the EIR for the SRWTP is found inadequate and impacts are reanalyzed. It is too speculative to draw any such conclusion at this point since additional studies would be required to substantiate any new significant impacts.

Because the SRWTP is planned to accommodate growth in Sacramento regional area by 2020, development in the SPA that occurs by 2020 would be accommodated by planned SRWTP capacity. Over time, additional planning at the SRWTP would occur, and overall capacity would be assessed and additional capacity planned for and added.

The SRWTP site has sufficient land area to accommodate a substantially higher flow than 218 mgd; however, future plans beyond the next 12 years are speculative.

There is expected to be sufficient SRWTP capacity to accommodate project flows under the Proposed Project, Resource Impact Minimization, Centralized Development, Reduced Hillside Development, and No USACE Permit Alternatives through 2020. There would be no assurances that the SRWTP would have adequate capacity for new wastewater flows for project development occurring after 2020. Therefore, the potential lack of treatment capacity past 2020 at full project buildout is a **direct, potentially significant** impact. The project would also contribute to the need to expand the facility and therefore would contribute **indirectly** to the **significant and unavoidable** short-term impact related to air quality from expansion of the SRWTP identified in the 2020 Master Plan EIR.

Mitigation Measure: Implement Mitigation Measure 3A.16-3.

RIM

As shown in Table 3A.16-3, implementation of the Resource Impact Minimization Alternative would generate 4.24 mgd of average dry-weather flow, and 9.38 mgd peak wet-weather flow (MacKay & Somps 2008b; Zoller, pers. comm.). The Resource Impact Minimization Alternative average-dry weather flow would be 1.34 mgd and peak-wet weather flow would be 2.61 mgd less than the Proposed Project Alternative.

The wastewater flows generated by the SPA, including the 189-acrea portion of the SPA that would be served by EID, have been planned for in the SRCSD Master Plan 2000. The master plan estimates that buildout of the SPA would generate an average dry-weather flow of 6.82 mgd a peak wet-weather flow of 14.48 mgd (SRCSD 2003b:Table 3-1). Because 189 acres of the SPA would be served by EID, the Resource Impact Minimization Alternative average-dry weather flow would be 2.58 mgd and peak-wet weather flow would be 5.1 mgd less than those identified in the SRCSD Master Plan 2000.

Collected wastewater flows from the SPA would ultimately be transported to the SRWTP for treatment and disposal. The 2020 Master Plan provides for the expansion of the SRWTP to 218 mgd based on growth rates expected to be achieved in the Sacramento County region by 2020. This projected capacity specifically includes project-related wastewater flows through 2020. At the time the 2020 Master Plan EIR was prepared, it was assumed that flows would increase from 155 mgd and would surpass 181 mgd by 2007. However, flows to the SRWTP have decreased between 2000 and 2008 from 155 mgd to 141 mgd.

Note that this total does not represent a buildout population total for SRCSD; rather, it represents the amount of growth expected within SRCSD based on projections. The SRCSD has determined that growth within the district is less than what was projected in the 2020 master plan and the SRWTP can provide capacity to future development beyond what was originally anticipated. If substantial population growth or new development occurs before 2020, the SRCSD will reevaluate expansion needs and phase treatment plant expansion to provide for sufficient long-term capacity.

SCRSD prepared the *Sacramento Regional Wastewater Treatment Plant 2020 Master Plan Final Environmental Impact Report* (SRCSD 2004). As described above, the EIR was determined to be legally deficient by the Sacramento Superior Court and the judgment has been appealed. The legal effect of the pending appeal is to stay the Superior Court's determination of legal deficiency. Thus, this EIR/EIS summarizes below and incorporates by reference the significant impacts that were identified in the 2020 Master Plan EIR as they relate to the project.

Because there is a relationship between the project and the need for expansion the SRWTP, implementation of the Resource Impact Minimization Alternative would contribute indirectly and incrementally to the related impacts (described above), most of which would be reduced to a less-than-significant level through implementation of mitigation measures. The only significant and unavoidable impact related to the treatment plant that was

identified would be from short-term increases in NO_X during construction of SRWTP facilities. In addition to this impact, there is a potential that new significant impacts to water quality could be identified if the EIR for the SRWTP is found inadequate and impacts are re-analyzed. It is too speculative to draw any such conclusion at this point since additional studies would be required to substantiate any new significant impacts.

Because the SRWTP is planned to accommodate growth in the Sacramento regional area by 2020, development in the SPA that occurs by 2020 would be accommodated by planned SRWTP capacity. Over time, additional planning at the SRWTP would occur, and overall capacity would be assessed and additional capacity planned for and added. There is expected to be sufficient SRWTP capacity to accommodate project flows under the Resource Impact Minimization Alternative through 2020. There would be no assurances that the SRWTP would have adequate capacity for new wastewater flows for project development occurring after 2020. Therefore, the potential lack of treatment capacity past 2020 at full project buildout is **direct** and **potentially significant**. The Resource Impact Minimization Alternative would also contribute to the need to expand the SRWTP facility and therefore would contribute **indirectly** to the **significant and unavoidable** short-term impact related to air quality from expansion of the SRWTP identified in the 2020 Master Plan EIR. ***[Lesser]***

Mitigation Measure: Implement Mitigation Measure 3A.16-3.

CD

As shown in Table 3A.16-3, implementation of the Centralized Development Alternative would generate 4.59 mgd of average dry-weather flow, and 9.96 mgd peak wet-weather flow (MacKay & Somps 2008b; Zoller, pers. comm.). The Centralized Development Alternative average-dry weather flow would be 0.99 mgd and peak-wet weather flow would be 2.03 mgd less than the Proposed Project Alternative.

The wastewater flows generated by the SPA, including the 189-acrea portion of the SPA that would be served by EID, have been planned for in the SRCSD Master Plan 2000. The master plan estimates that buildout of the SPA would generate an average dry-weather flow of 6.82 mgd a peak wet-weather flow of 14.48 mgd (SRCSD 2003b: Table 3-1). Because 189 acres of the SPA would be served by EID, the Centralized Development Alternative average-dry weather flow would be 2.23 mgd and peak-wet weather flow would be 4.52 mgd less than those identified in the SRCSD Master Plan 2000.

Collected wastewater flows from the SPA would ultimately be transported to the SRWTP for treatment and disposal. The 2020 Master Plan provides for the expansion of the SRWTP to 218 mgd based on growth rates expected to be achieved in the Sacramento County region by 2020. This projected capacity specifically includes project-related wastewater flows through 2020. At the time the 2020 Master Plan EIR was prepared, it was assumed that flows would increase from 155 mgd and would surpass 181 mgd by 2007. However, flows to the SRWTP have decreased between 2000 and 2008 from 155 mgd to 141 mgd.

Note that this total does not represent a buildout population total for SRCSD; rather, it represents the amount of growth expected within SRCSD based on projections. The SRCSD has determined that growth within the district is less than what was projected in the 2020 master plan and the SRWTP can provide capacity to future development beyond what was originally anticipated. If substantial population growth or new development occurs before 2020, the SRCSD will reevaluate expansion needs and phase treatment plant expansion to provide for sufficient long-term capacity.

SCRSD prepared the *Sacramento Regional Wastewater Treatment Plant 2020 Master Plan Final Environmental Impact Report* (SRCSD 2004). As described above, the EIR was determined to be legally deficient by the Sacramento Superior Court and the judgment has been appealed. The legal effect of the pending appeal is to stay the Superior Court's determination of legal deficiency. Thus, this EIR/EIS summarizes below and incorporates by reference the significant impacts that were identified in the 2020 Master Plan EIR as they relate to the project.

Because there is a relationship between the project and the need for expansion the SRWTP, implementation of the Centralized Development Alternative would contribute indirectly and incrementally to the related impacts (described above), most of which would be reduced to a less-than-significant level through implementation of mitigation measures. The only significant and unavoidable impact related to the treatment plant that was identified would be from short-term increases in NO_X during construction of SRWTP facilities. In addition to these impacts, there is a potential that new significant impacts to water quality could be identified if the EIR for the SRWTP is found inadequate and impacts are reanalyzed. It is too speculative to draw any such conclusion at this point since additional studies would be required to substantiate any new significant impacts.

Because the SRWTP is planned to accommodate growth in Sacramento regional area by 2020, development in the SPA that occurs by 2020 would be accommodated by planned SRWTP capacity. Over time, additional planning at the SRWTP would occur, and overall capacity would be assessed and additional capacity planned for and added. There is expected to be sufficient SRWTP capacity to accommodate project flows under the Centralized Development Alternative through 2020. However, there would be no assurances that the SRWTP would have adequate capacity for new wastewater flows for project development occurring after 2020. Therefore, the potential lack of treatment capacity past 2020 at full project buildout is a **direct, potentially significant** impact. The Centralized Development Alternative also would contribute to the need to expand the facility and therefore would contribute **indirectly** to the **significant and unavoidable** short-term impact related to air quality from expansion of the SRWTP identified in the 2020 Master Plan EIR. ***[Lesser]***

Mitigation Measure: Implement Mitigation Measure 3A.16-3.

RHD

As shown in Table 3A.16-3, implementation of the Reduced Hillside Development Alternative would generate 5.66 mgd of average dry-weather flow, and 11.96 mgd peak wet-weather flow (MacKay & Somps 2008b; Zoller, pers. comm.). The Reduced Hillside Development Alternative average-dry weather flow would be 0.08 mgd more than the Proposed Project Alternative and peak-wet weather flow would be 0.03 mgd less than the Proposed Project Alternative.

The wastewater flows generated by the SPA, including the 189-acrea portion of the SPA that would be served by EID, have been planned for in the SRCSD Master Plan 2000. The master plan estimates that buildout of the SPA would generate an average dry-weather flow of 6.82 mgd a peak wet-weather flow of 14.48 mgd (SRCSD 2003b:Table 3-1). Because 189 acres of the SPA would be served by EID, the Reduced Hillside Development Alternative average-dry weather flow would be 1.16 mgd and peak-wet weather flow would be 2.52 mgd less than those identified in the SRCSD Master Plan 2000.

Collected wastewater flows from the SPA would ultimately be transported to the SRWTP for treatment and disposal. The 2020 Master Plan provides for the expansion of the SRWTP to 218 mgd based on growth rates expected to be achieved in the Sacramento County region by 2020. This projected capacity specifically includes project-related wastewater flows through 2020. At the time the 2020 Master Plan EIR was prepared, it was assumed that flows would increase from 155 mgd and would surpass 181 mgd by 2007. However, flows to the SRWTP have decreased between 2000 and 2008 from 155 mgd to 141 mgd.

Note that this total does not represent a buildout population total for SRCSD; rather, it represents the amount of growth expected within SRCSD based on projections. The SRCSD has determined that growth within the district is less than what was projected in the 2020 master plan and the SRWTP can provide capacity to future development beyond what was originally anticipated. If substantial population growth or new development occurs before 2020, the SRCSD will reevaluate expansion needs and phase treatment plant expansion to provide for sufficient long-term capacity.

SCRSD prepared the *Sacramento Regional Wastewater Treatment Plant 2020 Master Plan Final Environmental Impact Report* (SRCSD 2004). As described above, the EIR was determined to be legally deficient by the Sacramento Superior Court and the judgment has been appealed. The legal effect of the pending appeal is to stay the Superior Court's determination of legal deficiency. Thus, this EIR/EIS summarizes below and incorporates by reference the significant impacts that were identified in the 2020 Master Plan EIR as they relate to the project.

Because there is a relationship between the project and the need for expansion the SRWTP, implementation of the Reduced Hillside Development Alternative would contribute indirectly and incrementally to the related impacts (described above), most of which would be reduced to a less-than-significant level through implementation of mitigation measures. The only significant and unavoidable impact related to the treatment plant that was identified would be from short-term increases in NO_X during construction of SRWTP facilities. In addition to these impacts, there is a potential that new significant impacts to water quality could be identified if the EIR for the SRWTP is found inadequate and impacts are reanalyzed. It is too speculative to draw any such conclusion at this point since additional studies would be required to substantiate any new significant impacts.

Because the SRWTP is planned to accommodate growth in Sacramento regional area by 2020, development in the SPA that occurs by 2020 would be accommodated by planned SRWTP capacity. Over time, additional planning at the SRWTP would occur, and overall capacity would be assessed and additional capacity planned for and added. There is expected to be sufficient SRWTP capacity to accommodate project flows under the Reduced Hillside Development Alternative through 2020. However, there would be no assurances that the SRWTP would have adequate capacity for new wastewater flows for project development occurring after 2020. Therefore, the potential lack of treatment capacity past 2020 at full project buildout is a **direct, potentially significant** impact. The Reduced Hillside Development Alternative would also contribute to the need to expand the facility and therefore would contribute **indirectly** to the **significant and unavoidable** short-term impact related to air quality from expansion of the SRWTP identified in the 2020 Master Plan EIR. ***[Greater]***

Mitigation Measure: Implement Mitigation Measure 3A.16-3.

Off-Site Elements

The sewer force main would provide the necessary infrastructure needed to provide wastewater service to the SPA, and construction of the off-site freeway interchange improvements, and the detention basin in Sacramento County, and the two roadway connections into El Dorado Hills would not involve construction of new housing or development of new businesses that would increase demand for wastewater collection and conveyance facilities. Therefore, the off-site elements would have a **direct, less-than-significant** impact on the increased demand wastewater treatment. The **indirect** physical impacts of constructing the sewer force main are addressed throughout this EIR/EIS in connection with discussions of the impacts of overall site development.

Mitigation Measure: No mitigation measures are required.

Implementation of Mitigation Measure 3A.16-3 would reduce direct significant impacts associated with increased demand for wastewater treatment plant facilities under the No USACE Permit, Proposed Project, Resource Impact Minimization, Centralized Development, and Reduced Hillside Development Alternatives to a **less-than-significant** level because an adequate wastewater treatment facilities would be documented before approval final maps and issuance of building permits.

Regarding expansion of the SRWTP, implementation of mitigation measures to reduce air quality impacts is the responsibility of SRCSD. Such measures would be implemented in accordance with the certified SRWTP 2020 Master Plan EIR. The No USACE Permit, Proposed Project, Resource Impact Minimization, Centralized Development, and Reduced Hillside Development Alternatives would indirectly contribute to impacts on air quality that would be **significant and unavoidable** after implementation of all feasible mitigation measures.

IMPACT 3A.16-4 **Increased Demand for EID Off-Site Wastewater Collection and Conveyance Facilities.** *The wastewater generated within the 189-acre EID service area would require off-site wastewater collection and conveyance facilities to the EID facility.*

On-Site Elements

NP

Under the No Project Alternative, development of up to 44 rural residences could occur under the existing Sacramento County agricultural zoning classification AG-80, and no off-site water facilities would be constructed. These residences would require the use of on-site septic systems and the SPA would be under the jurisdiction of Sacramento County, not El Dorado County. Therefore, the 44 individual rural residences that could be built under the No Project Alternative would not increase demand for municipal wastewater collection and conveyance facilities and there would be **no direct** or **indirect** impacts. See Section 3A.7, "Geology, Soils, Mineral, and Paleontological Resources - Land," for a discussion of the suitability of soils for use with septic systems. ***[Lesser]***

NCP, PP, RIM, CD, RHD

Approximately 189 acres of the SPA east of Empire Ranch Road is within the EID service area and off-site wastewater collection and conveyance facilities would be provided by EID. The wastewater infrastructure plan (MacKay & Somps 2008a) has identified three possible points of connection (POCs) to the existing EID conveyance system as described below.

- POC 1 would be to an existing 6-inch sewer main at Winterfield Court approximately 100 feet east of the SPA boundary. POC 1 would eliminate the need for Pump Station 4.
- POC 2 would be to an existing 6-inch sewer main at the intersection of Stonebriar Drive and Prima Way. POC 2 would eliminate the need for Pump Station 3.
- POC 3 would be to an existing 6-inch sewer main at Ranch Bluff Way south of White Rock Road. POC 3 would reduce flow to the East Sanitary Sewer Pump Station.

Sewer flows from the EID service area would be conveyed to an existing pump station at the intersection of White Rock Drive and Winterfield Drive and ultimately conveyed to the El Dorado Hills WWTP (see Impact 3A.16-5).

The existing collection and conveyance facilities may not have the capacity to accommodate wastewater flows generated by the project and could require improvements to meet project demands. Potential improvements include expanding the capacity of existing sewer pipelines, upgrading or replacing the existing pump, and installing an additional manhole; however, it is not known at this time what specific improvements would be required. Any improvements to these facilities would require additional analysis in a subsequent CEQA document to identify specific impacts and any required mitigation measures. Impacts resulting from improvements to EID collection and conveyance facilities could include: temporary, short-term generation of criteria air pollutants, such as PM_{10} (e.g., respirable particulate matter with a diameter smaller than 10 microns) and emissions of ozone precursors (e.g., reactive organic gases and oxides of nitrogen) during construction; temporary lane closures; increased truck traffic and other roadway impacts during construction; exposure of sensitive receptors to noise levels above noise ordinances during construction; exposure of sensitive noise receptors to new stationary-source noise from potential pump station improvements; and exposure of construction crews and the public to hazardous materials used in construction.

Because it is not known at this time if existing EID collection and conveyance facilities have the capacity to accommodate wastewater flows generated by project development and what improvements would be required, the

No USACE Permit, Proposed Project, Resource Impact Minimization, Centralized Development, and Reduced Hillside Development Alternatives could result in **direct** and **indirect, potentially significant** impacts related to improvements to off-site EID collection and conveyance facilities. ***[Similar]***

Mitigation Measure 3A.16-4: Submit Proof of Adequate EID Off-Site Wastewater Conveyance Facilities and Implement EID Off-Site Infrastructure Service Systems or Ensure That Adequate Financing Is Secured.

Before the approval of the final map and issuance of building permits for all project phases, the project applicant(s) of all project phases shall obtain proof from EID that an adequate wastewater conveyance system either has been constructed or is ensured through the use of bonds or other sureties. The project applicants of all project phases shall submit this proof to the City of Folsom. EID off-site wastewater conveyance infrastructure sufficient to provide adequate service to project shall be in place for the amount of development identified in the tentative map before approval of the final map and issuance of building permits for all project phases, or their financing shall be ensured to the satisfaction of the City.

Implementation: The project applicant(s) of all project phases.

Timing: Before approval of final maps and issuance of building permits for any project phase.

Enforcement: City of Folsom Community Development Department and City of Folsom Public Works Department.

Off-Site Elements

Construction of the off-site freeway interchange improvements, sewer force main, and the detention basin in Sacramento County, and the two roadway connections into El Dorado Hills would not involve construction of new housing or development of new businesses that would increase demand for EID off-site wastewater collection and conveyance facilities. Therefore, the off-site elements would have **no direct** or **indirect** impacts.

Mitigation Measure: No mitigation measures are required.

Implementation of Mitigation Measure 3A.16-4 would reduce significant impacts associated with increased demand for EID off-site wastewater collection facilities under the No USACE Permit, Proposed Project, Resource Impact Minimization, Centralized Development, and Reduced Hillside Development Alternatives to a **less-than-significant** level because adequate EID off-site wastewater conveyance facilities would be documented or adequate financing would be secured before approval final maps and issuance of building permits.

However, it is unknown if existing collection and conveyance facilities have the capacity to accommodate wastewater flows generated by project development and the project could directly and indirectly contribute to the need for off-site EID wastewater facility improvements. Therefore, the Proposed Project, Resource Impact Minimization, Centralized Development, Reduced Hillside Development, and No USACE Permit Alternatives would contribute to the potentially significant environmental effects associated with improvements to these facilities for which feasible mitigation may not be available to reduce impacts to a less-than-significant level. Therefore, this would be a **potentially significant and unavoidable** impact.

IMPACT 3A.16-5 Increased Demand for El Dorado Hills Wastewater Treatment Plant Facilities. *Project implementation would result in increased generation of wastewater. Collected wastewater flows from the 189-acre EID portion of the SPA would ultimately be transported to the El Dorado Hills WWTP for treatment and disposal.*

On-Site Elements

NP

Under the No Project Alternative, development of up to 44 rural residences could occur under the existing Sacramento County agricultural zoning classification AG-80, and no off-site water facilities would be constructed. These residences would require the use of on-site septic systems and the SPA would be under the jurisdiction of Sacramento County, not El Dorado County. Therefore, the 44 individual rural residences that could be built under the No Project Alternative would not increase demand for municipal wastewater treatment facilities and there would be **no direct** or **indirect** impacts. See Section 3A.7, "Geology, Soils, Mineral, and Paleontological Resources - Land," for a discussion of the suitability of soils for use with septic systems. ***[Lesser]***

NCP

As shown in Table 3A.16-3, implementation of the No USACE Permit Alternative would generate 0.31 mgd of average dry-weather flow and 0.78 mgd peak wet-weather flow within the EID service area (Zoller, pers. comm. 2009). The No USACE Permit Alternative average-dry weather flow would be 0.03 mgd and peak-wet weather flow would be 0.08 mgd more than the Proposed Project Alternative.

Collected wastewater flows from the EID portion of the SPA would ultimately be transported to the El Dorado Hills WWTP for treatment and disposal. Currently, the El Dorado Hills WWTP's design capacity is 3.0 mgd average dry-weather flow and 7.6 mdg peak wet-weather flow. As of 2007, the average dry weather flow is approximately 2.86 and the peak wet-weather flow is 8.04 mgd. Expansion of the WWTP is required to provide wastewater treatment capacity for land uses in El Dorado Hills as identified by the El Dorado County General Plan (2003), to meet anticipated regulatory requirements for water quality, and to help meet recycled water demands. The treatment plant is currently being expanded to 4.0 mgd, which is anticipated to be completed in December 2009. The full buildout of the treatment plant to 5.4 mgd is expected to occur by 2025.

The SPA was not included in the planned future capacity of the El Dorado Hills WWTP; therefore, the No USACE Permit Alternative would potentially result in increased in wastewater flows that exceed treatment plant capacity. Any improvements the treatment plant would require additional analysis in a separate CEQA document to identify specific impacts and any required mitigation measures. Potential impacts that could result from improvements to the El Dorado Hills WWTP are described above. Because it is not known at this time if the existing El Dorado Hills WWTP has the capacity to treat wastewater flows generated by project development and what improvements would be required, the No USACE Permit Alternative could result in **direct** and **indirect, potentially significant** impacts related to improvements to the El Dorado Hills WWTP. ***[Greater]***

Mitigation Measure 3A.16-5: Demonstrate Adequate El Dorado Hills Wastewater Treatment Plant Capacity.

The project applicant(s) of all project phases shall demonstrate adequate capacity at the El Dorado Hills WWTP for new wastewater flows generated by project development. This shall involve preparing a tentative map–level study and paying connection and capacity fees as identified by EID. Approval of the final map and issuance of building permits for all project phases shall not be granted until the City verifies adequate El Dorado Hills WWTP capacity is available for the amount of development identified in the tentative map.

Implementation: The project applicant(s) of all project phases.

Timing: Before approval of final maps and issuance of building permits for any project phases involving the El Dorado Hills WWTP.

Enforcement: City of Folsom Community Development Department and City of Folsom Public Works Department.

PP

As shown in Table 3A.16-3, implementation of the Proposed Project Alternative would generate 0.28 mgd of average dry-weather flow and 0.70 mgd peak wet-weather flow within the EID service area (MacKay & Somps 2008b). Collected wastewater flows from the EID portion of the SPA would ultimately be transported to the El Dorado Hills WWTP for treatment and disposal.

Currently, the design capacity of the El Dorado Hills WWTP is 3.0 mgd average dry-weather flow and 7.6 mdg peak wet-weather flow. As of 2007, the average dry weather flow is approximately 2.86 and the peak wet-weather flow is 8.04 mgd. Expansion of the WWTP is required to provide wastewater treatment capacity for land uses in El Dorado Hills as identified by the El Dorado County General Plan (2003), to meet anticipated regulatory requirements for water quality, and to help meet recycled water demands. The treatment plant is currently being expanded to 4.0 mgd, which is anticipated to be completed in December 2009. The full buildout of the treatment plant to 5.4 mgd is expected to occur by 2025.

The SPA was not included in the planned future capacity of the El Dorado Hills WWTP; therefore, the Proposed Project Alternative would potentially result in increased in wastewater flows that exceed treatment plant capacity. Any improvements the treatment plant would require additional analysis in a separate CEQA document to identify specific impacts and any required mitigation measures. Impacts resulting from improvements to the El Dorado Hills WWTP could include: temporary, short-term generation of criteria air pollutants, such as PM_{10} and emissions of ozone precursors (e.g., reactive organic gases and oxides of nitrogen) during construction; generation of new odors from operation of expanded treatment plant facilities; degradation of water quality from increased discharges to Carson Creek; temporary roadway lane closures, increased truck traffic, and other roadway impacts during construction; exposure of sensitive receptors to noise levels above noise ordinances during construction; and exposure of construction crews and the public to hazardous materials used in construction.

Because it is not known at this time if the existing El Dorado Hills WWTP has the capacity to treat wastewater flows generated by project development and what improvements would be required, the Proposed Project Alternative could result in **direct** and **indirect, potentially significant** impacts related improvements to the El Dorado Hills WWTP.

Mitigation Measure: Implement Mitigation Measure 3A.16-5.

RIM

As shown in Table 3A.16-3, implementation of the Resource Impact Minimization Alternative would generate 0.22 mgd of average dry-weather flow and 0.55 mgd peak wet-weather flow within the EID service area (MacKay & Somps 2008b). The Resource Impact Minimization Alternative average-dry weather flow would be 0.06 mgd and peak-wet weather flow would be 0.15 mgd less than the Proposed Project Alternative.

Collected wastewater flows from the EID portion of the SPA would ultimately be transported to the El Dorado Hills WWTP for treatment and disposal. Currently, the design capacity of the El Dorado Hills WWTP is 3.0 mgd average dry-weather flow and 7.6 mgd peak wet-weather flow. As of 2007, the average dry weather flow is approximately 2.86 and the peak wet-weather flow is 8.04 mgd. Expansion of the WWTP is required to provide wastewater treatment capacity for land uses in El Dorado Hills as identified by the El Dorado County General Plan (2003), to meet anticipated regulatory requirements for water quality, and to help meet recycled water demands. The treatment plant is currently being expanded to 4.0 mgd, which is anticipated to be completed in December 2009. The full buildout of the treatment plant to 5.4 mgd is expected to occur by 2025.

The SPA was not included in the planned future capacity of the El Dorado Hills WWTP; therefore, the Resource Impact Minimization Alternative would potentially result in increased in wastewater flows that exceed treatment plant capacity. Any improvements the treatment plant would require additional analysis in a separate CEQA document to identify specific impacts and any required mitigation measures. Potential impacts that could occur as a result of improvements to the El Dorado Hills WWTP are described above. Because it is not known at this time if the existing El Dorado Hills WWTP has the capacity to treat wastewater flows generated by project development and what improvements would be required, the Resource Impact Minimization Alternative could result in **direct** and **indirect, potentially significant** impacts related to improvements to the El Dorado Hills WWTP. ***[Lesser]***

Mitigation Measure: Implement Mitigation Measure 3A.16-5.

CD

As shown in Table 3A.16-3, implementation of the Centralized Development Alternative would generate 0.05 mgd of average dry-weather flow and 0.14 mgd peak wet-weather flow within the EID service area (Zoller, pers. comm. 2009). The Centralized Development Alternative average-dry weather flow would be 0.23 mgd and peak-wet weather flow would be 0.56 mgd less than the Proposed Project Alternative.

Collected wastewater flows from the EID portion of the SPA would ultimately be transported to the El Dorado Hills WWTP for treatment and disposal. Currently, the design capacity of the El Dorado Hills WWTP is 3.0 mgd average dry-weather flow and 7.6 mgd peak wet-weather flow. As of 2007, the average dry weather flow is approximately 2.86 and the peak wet-weather flow is 8.04 mgd. Expansion of the WWTP is required to provide wastewater treatment capacity for land uses in El Dorado Hills as identified by the El Dorado County General Plan (2003), to meet anticipated regulatory requirements for water quality, and to help meet recycled water demands. The treatment plant is currently being expanded to 4.0 mgd, which is anticipated to be completed in December 2009. The full buildout of the treatment plant to 5.4 mgd is expected to occur by 2025.

The SPA was not included in the planned future capacity of the El Dorado Hills WWTP; therefore, the Centralized Development Alternative would potentially result in increased in wastewater flows that exceed treatment plant capacity. Any improvements the treatment plant would require additional analysis in a separate CEQA document to identify specific impacts and any required mitigation measures. Potential impacts that could result from improvements to the El Dorado Hills WWTP are described above. Because it is not known at this time if the existing El Dorado Hills WWTP has the capacity to treat wastewater flows generated by project development and what improvements would be required, the Centralized Development Alternative could result in **direct** and **indirect, potentially significant** impacts related to improvements to the El Dorado Hills WWTP. ***[Lesser]***

Mitigation Measure: Implement Mitigation Measure 3A.16-5.

RHD

As shown in Table 3A.16-3, implementation of the Reduced Hillside Development Alternative would generate 0.23 mgd of average dry-weather flow and 0.59 mgd peak wet-weather flow within the EID service area (Zoller, pers. comm. 2009). The Reduced Hillside Development Alternative average-dry weather flow would be 0.05 mgd and peak-wet weather flow would be 0.11 mgd less than the Proposed Project Alternative.

Collected wastewater flows from the EID portion of the SPA would ultimately be transported to the El Dorado Hills WWTP for treatment and disposal. Currently, the El Dorado Hills WWTP's design capacity is 3.0 mgd average dry-weather flow and 7.6 mdg peak wet-weather flow. As of 2007, the average dry weather flow is approximately 2.86 and the peak wet-weather flow is 8.04 mgd. Expansion of the WWTP is required to provide wastewater treatment capacity for land uses in El Dorado Hills as identified by the El Dorado County General

Plan (2003), to meet anticipated regulatory requirements for water quality, and to help meet recycled water demands. The treatment plant is currently being expanded to 4.0 mgd, which is anticipated to be completed in December 2009. The full buildout of the treatment plant to 5.4 mgd is expected to occur by 2025.

The SPA was not included in the planned future capacity of the El Dorado Hills WWTP; therefore, the Reduced Hillside Development Alternative would potentially result in increased in wastewater flows that exceed treatment plant capacity. Any improvements the treatment plant would require additional analysis in a separate CEQA document to identify specific impacts and any required mitigation measures. Potential impacts that could result from improvements to the El Dorado Hills WWTP are described above. Because it is not known at this time if the existing El Dorado Hills WWTP has the capacity to treat wastewater flows generated by project development and what improvements would be required, the Reduced Hillside Development Alternative could result in **direct** and **indirect, potentially significant** impacts related to improvements to the El Dorado Hills WWTP. ***[Lesser]***

Mitigation Measure: Implement Mitigation Measure 3A.16-5.

Off-Site Elements

Construction of the off-site freeway interchange improvements, sewer force main, and the detention basin in Sacramento County, and the two roadway connections into El Dorado Hills would not involve construction of new housing or development of new businesses that would increase demand for off-site EID wastewater collection and conveyance facilities. Therefore, **no direct** or **indirect** impacts would occur.

Mitigation Measure: No mitigation measures are required.

Implementation of Mitigation Measure 3A.16-5 would reduce significant impacts associated with increased demand for wastewater treatment plant facilities under the No USACE Permit, Proposed Project, Resource Impact Minimization, Centralized Development, and Reduced Hillside Development Alternatives to a **less-than-significant** level because adequate wastewater treatment facilities would be documented before approval final maps and issuance of building permits.

However, it is unknown if existing the El Dorado Hills WWTP has the capacity to accommodate wastewater flows generated by project development, and the project could directly and indirectly contribute to the need for El Dorado Hills WWTP improvements. Therefore, the No USACE Permit, Proposed Project, Resource Impact Minimization, Centralized Development, and Reduced Hillside Development Alternatives could contribute to the potentially significant environmental effects associated with improvements to treatment plant facilities for which feasible mitigation may not be available to reduce impacts to a less-than-significant level. Therefore, this would be a **potentially significant and unavoidable** impact.

IMPACT 3A.16-6 Short-Term Generation of Solid Waste during Project Construction. *Project construction would generate short-term construction-related debris and waste.*

On-Site and Off-Site Elements

NP

Under the No Project Alternative, development of up to 44 rural residences could occur under the existing Sacramento County agricultural zoning classification AG-80, and no off-site water facilities would be constructed. Construction of 44 individual rural residences within a 3,500-acre area would represent a very small amount of construction-related debris and waste in the SPA. Solid waste generate from construction of these rural residences would be disposed of at the Keifer Landfill, and the Kiefer Landfill has sufficient permitted capacity to accommodate the disposal needs that would be generated under the No Project Alternative. Therefore, the 44 individual rural residences that could be built under the No Project Alternative would have a **direct, less-than-**

significant impact on short-term construction-related debris and waste; **no indirect** impacts would occur. ***[Lesser]***

NCP, PP, RIM, CD, RHD

Project construction activities would occur at intervals over the 19-year buildout period. CIWMB calculates solid waste business generation rates based on Federal standard industrial classifications and averages of samples from individual businesses throughout California. CIWMB estimates that construction activities typically generate an average of approximately 3,258 tons per year of solid waste; therefore, construction activities would generate a total of 61,902 tons per year (19 × 3,258) or 169.5 tpd over the buildout period (2011–2030) (CIWMB 2008e).

Solid waste generated by construction activities in the SPA and by construction of the off-site freeway interchanges improvements, the sewer force main, and the detention basin in Sacramento County and Folsom would be disposed of at the Kiefer Landfill. The landfill is permitted to accept 10,800 maximum tpd of solid waste with an average intake of 6,000 tpd. The estimated range of solid waste generated by construction activities (169.5 tpd) during the 19-year buildout period would be approximately 1.6% of the 10,800 maximum tpd that could be received at the landfill. The landfill has a total capacity of 117 million cubic yards, and a remaining capacity of 113 million cubic yards. Currently, the landfill has a closure date of 2064.

In addition, the project would be required to comply with the County's Construction and Demolition Ordinance (Title 6, Chapter 6.20) and City's Construction and Demolition Recycling Ordinance (Title 8, Chapter 8.30). Contractors are required to document types of building materials and estimated quantities on a "Waste Management Plan" before obtaining building permits; within 30 days of project completion contractors must complete the "Waste Management Plan" to document the actual quantity of construction or demolition waste generated and demonstrate the actual quantities recycled, salvaged or reused, and/or disposed.

Any solid waste generated by construction of the two roadway connections into El Dorado Hills would be disposed of at the Lockwood Regional Landfill located in Sparks, Nevada. The Lockwood Regional Landfill receives 1.4 million tons of solid waste per year, with a daily average of 7,700 tons. The existing permit does not restrict the maximum daily and yearly tonnage that may be received by the landfill and the facility has a remaining capacity of 32.5 million tons. Currently, the landfill has a projected closure date of 2035. In addition, the roadway connections into El Dorado County would be required to comply with the County's Construction and Demolition Debris Recycling Ordinance (Title 8, Chapter 8.43). This ordinance requires that a "Debris Recycling Acknowledgment" be submitted for review and approval at the time of submitting an application for a building permit. Within 60 days after completion and/or occupancy, contractors must submit a "Debris Recycling Report" to document the actual quantity of construction or demolition wastes generated and demonstrate the actual quantities recycled, salvaged or reused, and/or disposed.

Because the Kiefer Landfill and the Lockwood Landfill have sufficient permitted capacity to accommodate short-term construction-related disposal needs for the on-site and off-site elements, and because the project would comply with the City's Construction and Demolition Debris Recycling Ordinance and County's Construction and Demolition Debris Recycling Ordinance, this **direct** impact is **less than significant**. **No indirect** impacts would occur. ***[Similar]***

Mitigation Measure: No mitigation measures are required.

IMPACT 3A.16-7 Increased Long-Term Generation of Solid Waste. *Project implementation would increase long-term solid-waste generation.*

On-Site Elements

NP

Under the No Project Alternative, development of up to 44 rural residences could occur under the existing Sacramento County agricultural zoning classification AG-80, and no off-site water facilities would be constructed. Construction of 44 individual rural residences could potentially generate an increased population of 128 persons in Sacramento County. Based on CIWMB's generation rates for Sacramento County (0.36 ton per resident per year), the estimated total population for the No Project Alternative (128 persons) would generate approximately 46.1 tons of solid waste per year (0.36 × 128), or 0.1 tpd, which would be 32,493 tons per year (89.0 tpd) less than would be generated under the Proposed Project Alternative.

As described above, solid waste collected from the SPA would be hauled to the Kiefer Landfill, which is permitted to accept 10,800 maximum tpd of solid waste. The estimated 0.1 tpd of solid waste generated by the No Project Alternative would be approximately 0.0001% of the 10,800 maximum tpd that could be received at the landfill. Therefore, this landfill has sufficient permitted capacity to accommodate solid-waste disposal needs for the No Project Alternative, and this would be a **direct, less-than-significant** impact on construction-related soil erosion; **no indirect** impacts would occur. ***[Lesser]***

NCP

Based on the CIWMB's generation rates for Sacramento County, the estimated total population for the No USACE Permit Alternative (15,808) would generate approximately 5,691 tons of solid waste per year (0.36 × 15,808), or 15.6 tpd. The No USACE Permit Alternative would generate a maximum of approximately 13,021 jobs over the 19-year buildout period. Based on an average generation rate of 1.8 tons per employee per year, the No USACE Permit Alternative would generate 23,438 tons of waste per year (1.8 × 13,021) or 64.2 tpd in the SPA. As shown on Table 3A.16-4, combining residential and business solid-waste generation, the total solid-waste generation for the No USACE Permit Alternative would be approximately 29,399 tons per year (80.7 tpd), which would be 3,140 tons per year (9.3 tpd) less than would be generated under the Proposed Project Alternative. Much lower generation rates would occur at project initiation, with gradual increases in the rate as development progressed.

Solid waste collected from the SPA would be hauled to the Kiefer Landfill, which is permitted to accept 10,800 maximum tpd of solid waste. The estimated 79.8 tpd of solid waste generated by the No USACE Permit Alternative would be approximately 0.7% of the 10,800 maximum tpd that could be received at the landfill. Therefore, this landfill has sufficient permitted capacity to accommodate solid-waste disposal needs for the No USACE Permit Alternative. Development of the No USACE Permit Alternative would also be required to comply with all Federal, state, and local statutes and regulations related to solid-waste reduction and recycling. Therefore, this **direct** impact is considered **less than significant**. **No indirect** impacts would occur. ***[Lesser]***

Mitigation Measure: No mitigation measures are required.

PP

Based on CIWMB's generation rates for Sacramento County (0.36 ton per resident per year), the estimated total population for the Proposed Project Alternative (24,335 persons) would generate approximately 8,761 tons of solid waste per year (0.36 × 24,335), or 24.0 tpd.

The Proposed Project Alternative would generate a maximum of approximately 13,210 jobs over the 19-year buildout period. The employees in the SPA would be working in jobs within designated waste categories such as commercial/retail stores (0.3 ton of waste per employee per year), other professional services (1.2 tons of waste per employee per year), business services (1.7 tons of waste per employee per year), and restaurants (3.1 tons of waste per employee per year). To estimate a single business waste–disposal rate for project development, the two anticipated extremes among the categories (0.3 ton and 3.1 tons per employee per year) were averaged, resulting in a generation rate of 1.8 tons per employee per year. An average business waste disposal rate of 1.8 tons per employee per year results in generation of 23,778 tons of waste per year (1.8 × 13,210) or 65.1 tpd in the SPA.

As shown on Table 3A.16-4, combining residential and business solid-waste generation, total solid-waste generation for the Proposed Project Alternative would be approximately 32,539 tons per year (89.1 tpd). Much lower generation rates would occur at project initiation, with gradual increases in the rate as development progressed. As described above, solid waste collected from the SPA would be hauled to the Kiefer Landfill, which is permitted to accept 10,800 maximum tpd of solid waste. The estimated 89.1 tpd of solid waste generated by the Proposed Project Alternative would be approximately 0.8% of the 10,800 maximum tpd that could be received at the landfill. Therefore, this landfill has sufficient permitted capacity to accommodate solid-waste disposal needs for the Proposed Project Alternative. Development of the Proposed Project Alternative would also be required to comply with all Federal, state, and local statutes and regulations related to solid-waste reduction and recycling. Therefore, this **direct** impact is considered **less than significant**. **No indirect** impacts would occur.

Mitigation Measure: No mitigation measures are required.

RIM

Based on the CIWMB's generation rates for Sacramento County, the estimated total population for the Resource Impact Minimization Alternative (19,584 people) would generate approximately 7,050 tons of solid waste per year (0.36 × 19,584), or 19.3 tpd. The Resource Impact Minimization Alternative would generate a maximum of approximately 9,749 jobs over the 19-year buildout period. Based on an average generation rate of 1.8 tons per employee per year, the Resource Impact Minimization Alternative would generate 17,548 tons of waste per year (1.8 × 9,749) or 48.0 tpd in the SPA. As shown on Table 3A.16-4, combining residential and business solid-waste generation, the total solid-waste generation for the Resource Impact Minimization Alternative would be approximately 24,598 tons per year (67.3 tpd), which would be 7,950 tons per year (21.8 tpd) less than would be generated under the Proposed Project Alternative. Much lower generation rates would occur at project initiation, with gradual increases in the rate as development progressed.

Solid waste collected from the SPA would be hauled to the Kiefer Landfill, which is permitted to accept 10,800 maximum tpd of solid waste. The estimated 67.3 tpd of solid waste generated by the Resource Impact Minimization Alternative would be approximately 0.6% of the 10,800 maximum tpd that could be received at the landfill. Therefore, this landfill has sufficient permitted capacity to accommodate solid-waste disposal needs for the Resource Impact Minimization Alternative. Development of the Resource Impact Minimization Alternative would also be required to comply with all Federal, state, and local statutes and regulations related to solid-waste reduction and recycling. Therefore, this **direct** impact is considered **less than significant**. **No indirect** impacts would occur. ***[Lesser]***

Mitigation Measure: No mitigation measures are required.

CD

Based on the CIWMB's generation rates for Sacramento County, the estimated total population for the Centralized Development Alternative (20,689) would generate approximately 7,448 tons of solid waste per year (0.36 × 20,689), or 20.4 tpd. The Centralized Development Alternative would generate a maximum of approximately 16,860 jobs over the 19-year buildout period. Based on an average generation rate of 1.8 tons per

employee per year, the Centralized Development Alternative would generate 30,348 tons of waste per year (1.8 × 16,860) or 83.1 tpd in the SPA. As shown on Table 3A.16-4, combining residential and business solid-waste generation, the total solid-waste generation for the Centralized Development Alternative would be approximately 37,796 tons per year (103.5 tpd), which would be 5,257 tons per year (14.4 tpd) more than would be generated under the Proposed Project Alternative. Much lower generation rates would occur at project initiation, with gradual increases in the rate as development progressed.

Solid waste collected from the SPA would be hauled to the Kiefer Landfill, which is permitted to accept 10,800 maximum tpd of solid waste. The estimated 103.5 tpd of solid waste generated by the Centralized Development Alternative would be approximately 1.0% of the 10,800 maximum tpd that could be received at the landfill. Therefore, this landfill has sufficient permitted capacity to accommodate solid-waste disposal needs for the Centralized Development Alternative. Development of the Centralized Development Alternative would also be required to comply with all Federal, state, and local statutes and regulations related to solid-waste reduction and recycling. Therefore, this **direct** impact is considered **less than significant**. **No indirect** impacts would occur. ***[Greater]***

Mitigation Measure: No mitigation measures are required.

RHD

Based on the CIWMB's generation rates for Sacramento County, the estimated total population for the Reduced Hillside Development Alternative (25,022) would generate approximately 9,008 tons of solid waste per year (0.36 × 25,022), or 24.7 tpd. The Reduced Hillside Development Alternative would generate a maximum of approximately 17,484 jobs over the 19-year buildout period. Based on an average generation rate of 1.8 tons per employee per year, the Reduced Hillside Development Alternative would generate 31,471 tons of waste per year (1.8 × 17,484) or 86.2 tpd in the SPA. As shown on Table 3A.16-4, combining residential and business solid-waste generation, the total solid-waste generation for the Reduced Hillside Development Alternative would be approximately 40,479 tons per year (110.9 tpd), which would be 7,940 tons per year (21.8 tpd) more than would be generated under the Proposed Project Alternative. Much lower generation rates would occur at project initiation, with gradual increases in the rate as development progressed.

Solid waste collected from the SPA would be hauled to the Kiefer Landfill, which is permitted to accept 10,800 maximum tpd of solid waste. The estimated 110.9 tpd of solid waste generated by the Reduced Hillside Development Alternative would be approximately 1.0% of the 10,800 maximum tpd that could be received at the landfill. Therefore, this landfill has sufficient permitted capacity to accommodate solid-waste disposal needs for the Reduced Hillside Development Alternative. Development of the Reduced Hillside Development Alternative would also be required to comply with all Federal, state, and local statutes and regulations related to solid-waste reduction and recycling. Therefore, this **direct** impact is considered **less than significant**. **No indirect** impacts would occur. ***[Greater]***

Mitigation Measure: No mitigation measures are required.

Off-Site Elements

Construction of the off-site freeway interchange improvements, the sewer force main, the detention basin in Sacramento County, and the two roadway connections into El Dorado Hills would not involve construction of new housing or development of new businesses. Therefore, the off-site elements would have **no direct** or **indirect** impact on increased long-term generation of solid waste.

Mitigation Measure: No mitigation measures are required.

IMPACT 3A.16-8 Increased Demand for Electricity and Infrastructure. *Project implementation would increase the demand for electricity and electrical infrastructure.*

On-Site Elements

NP

Under the No Project Alternative, development of up to 44 rural residences could occur under the existing Sacramento County agricultural zoning classification AG-80, and no off-site water facilities would be constructed. Construction of 44 individual rural residences within a 3,500-acre area would represent a very small increase in demand for electricity. The proposed dwelling units would require an average of 0.1 MVA (megavolt amperes) and a peak demand of 0.2 MVA. The average electrical demands of the No Project Alternative would be 39.6 MVA and peak electrical demands would be 87.1 MVA less than the Proposed Project Alternative.

Individual property owners would be required to coordinate with SMUD to obtain electrical service. Because the 44 individual rural residences that could be built under the No Project Alternative would result in minimal increases in demand for electricity and because individual property owners would coordinate with SMUD regarding service, this **direct** impact is considered **less than significant**. **No indirect** impacts would occur. ***[Lesser]***

NCP

Buildout of the No USACE Permit Alternative would increase electrical demand in the SMUD service area by an average of 35.7 MVA with a peak demand of 78.0 MVA (Table 3A.16-5). This alternative would have an average electrical demand of 4.0 MVA and peak electrical demand of 9.3 MVA less than the Proposed Project Alternative.

SMUD currently has existing capacity to serve the project from its electrical distribution system north of U.S. 50. To serve the remainder of the SPA, SMUD has determined that a minimum of three distribution substations would be required to serve project development as described above (Kim, pers. comm., 2009). The on-site service lines would be sized to meet the demands of project development, and public utility easements would be dedicated for all underground facilities. SMUD would extend lines and construct facilities to serve the SPA concurrently with development phases, and the location of this infrastructure would be identified in the final project design. As part of the project approval process, the project applicants of all project phases would coordinate with and meet the requirements of SMUD regarding the extension and locations of on-site infrastructure.

The proposed electrical-utility improvements would be required to comply with all existing City and SMUD requirements, and applicable requirements of the California Building Standards Code. Because SMUD would meet the electrical demands of the No USACE Permit Alternative and provide new electrical infrastructure to the SPA, this **direct** impact is **less than significant**. The **indirect** physical impacts of constructing these facilities are addressed throughout this EIR/EIS in connection with discussions of the impacts of overall site development. ***[Lesser]***

Mitigation Measure: No mitigation measures are required.

PP

Implementation of the Proposed Project Alternative would increase electrical demand in the SPA. Electrical service in Folsom is provided by SMUD through 473 miles of transmission lines (110 kV or more) and 9,784 miles of distribution lines (typically 12 kV). As shown on Table 3A.16-5, buildout of the Proposed Project Alternative would increase in electrical demand in the SMUD service area by an average of 39.7 MVA with and a peak demand of 87.3 MVA (Capitol Utilities Specialists 2009:4). SMUD concurs with this assessment; however,

SMUD has calculated the worst-case scenario as increasing electrical demand by a total of 120 MVA (Capitol Utilities Specialists 2009:5; Kim, pers. comm., 2009).

SMUD currently has the following electrical infrastructure on and in the vicinity of the SPA: a 69-kV overhead single-circuit transmission line located in the south-central portion of the SPA, a 69-kV single-circuit transmission line that extends south and west along Prairie City Road until it reaches White Rock Road, a 69-kV single-circuit transmission line that extends south from U.S. 50 on the east side of Placerville Road where it terminates just within the SPA, and a 12-kV overhead transmission line that extends north from White Rock Road along the east side of Placerville Road to U.S. 50.

SMUD currently has existing capacity to serve the Proposed Project Alternative from its electrical distribution system north of U.S. 50 (Capitol Utility Specialists 2009:5). To serve the remainder of the SPA, SMUD has determined that a minimum of three distribution substations would be required to serve the proposed development (Kim, pers. comm., 2009). These substations would be located in the vicinity of Easton Valley Parkway and Rowberry Drive, near the intersection of White Rock Road and Scott Road, and along Placerville Road just north of Easton Valley Road. Each substation would have two 25 MVA and eight underground 12-kV mainline circuits. Electrical distribution feeders would extend from these substations to serve the SPA (Capitol Utility Specialists 2009:4).

A new 69-kV overhead transmission line would be constructed along Placerville Road from U.S. 50 to White Rock Road. Additional overhead transmission lines may be required depending on the location of the distribution substations (Kim, pers. comm., 2009). SMUD would install new electrical mainline facilities and underground the existing 12-kV overhead transmission line concurrently with improvements to White Rock Road (Capitol Utility Specialists 2009:3). SMUD would conduct a separate CEQA analysis to analyze specific impacts and identify any required mitigation measures for construction and operation of new off-site electrical facilities.

The on-site service lines would be sized to meet the demands of project development, and public utility easements would be dedicated for all underground facilities. SMUD would extend lines and construct facilities to serve the SPA concurrently with development phases, and the location of this infrastructure would be identified in the final project design. As part of the project approval process, the project applicant(s) of all project phases would coordinate with and meet the requirements of SMUD regarding the extension and locations of on-site infrastructure (as more fully described in Chapter 2, “Alternatives”).

The proposed electrical-utility improvements would be required to comply with all existing City and SMUD requirements, and applicable requirements of the California Building Standards Code. Because SMUD would meet the electrical demands of the Proposed Project Alternative and provide new electrical infrastructure to the SPA, this **direct** impact is **less than significant**. The **indirect** physical impacts of constructing these facilities are addressed throughout this EIR/EIS in connection with discussions of the impacts of overall site development.

Mitigation Measure: No mitigation measures are required.

RIM

Buildout of the Resource Impact Minimization Alternative would increase electrical demand in the SMUD service area by an average of 34.5 MVA with a peak demand of 75.9 MVA (Table 3A.16-5). This alternative would have an average electrical demand of 5.2 MVA and peak electrical demand of 11.4 MVA less than the Proposed Project Alternative.

SMUD currently has existing capacity to serve the project from its electrical distribution system north of U.S. 50. To serve the remainder of the SPA, SMUD has determined that a minimum of three distribution substations would be required to serve the project development, as described above (Kim, pers. comm., 2009). The on-site service lines would be sized to meet the demands of project development, and public utility easements would be

dedicated for all underground facilities. SMUD would extend lines and construct facilities to serve the SPA concurrently with development phases, and the location of this infrastructure would be identified in the final project design. As part of the project approval process, the project applicants of all project phases would coordinate with and meet the requirements of SMUD regarding the extension and locations of on-site infrastructure.

The proposed electrical-utility improvements would be required to comply with all existing City and SMUD requirements, and applicable requirements of the California Building Standards Code. Because SMUD would meet the electrical demands of the Resource Impact Minimization Alternative and provide new electrical infrastructure to the SPA, this **direct** impact is **less than significant**. The **indirect** physical impacts of constructing these facilities are addressed throughout this EIR/EIS in connection with discussions of the impacts of overall site development. ***[Lesser]***

Mitigation Measure: No mitigation measures are required.

CD

Buildout of the Centralized Development Alternative would increase electrical demand in the SMUD service area by an average of 45.1 MVA with a peak demand of 97.1 MVA (Table 3A.16-5). This alternative would have an average electrical demand of 5.4 MVA and peak electrical demand of 9.8 MVA more than the Proposed Project Alternative.

SMUD currently has existing capacity to serve the project from its electrical distribution system north of U.S. 50. To serve the remainder of the SPA, SMUD has determined that a minimum of three distribution substations would be required to serve the project development as described above (Kim, pers. comm., 2009). The on-site service lines would be sized to meet the demands of project development, and public utility easements would be dedicated for all underground facilities. SMUD would extend lines and construct facilities to serve the SPA concurrently with development phases, and the location of this infrastructure would be identified in the final project design. As part of the project approval process, the project applicants of all project phases would coordinate with and meet the requirements of SMUD regarding the extension and locations of on-site infrastructure.

The proposed electrical-utility improvements would be required to comply with all existing City and SMUD requirements, and applicable requirements of the California Building Standards Code. Because SMUD would meet the electrical demands of the Centralized Development Alternative and provide new electrical infrastructure to the SPA, this **direct** impact is **less than significant**. The **indirect** physical impacts of constructing these facilities are addressed throughout this EIR/EIS in connection with discussions of the impacts of overall site development. ***[Greater]***

Mitigation Measure: No mitigation measures are required.

RHD

Buildout of the Reduced Hillside Development Alternative would increase electrical demand in the SMUD service area by an average of 52.0 MVA with a peak demand of 111.5 MVA (Table 3A.16-5). This alternative would have an average electrical demand of 12.3 MVA and peak electrical demand of 24.2 MVA more than the Proposed Project Alternative.

SMUD currently has existing capacity to serve the project from its electrical distribution system north of U.S. 50. To serve the remainder of the SPA, SMUD has determined that a minimum of three distribution substations would be required to serve project developed as described above (Kim, pers. comm., 2009). The on-site service lines would be sized to meet the demands of project development, and public utility easements would be

dedicated for all underground facilities. SMUD would extend lines and construct facilities to serve the SPA concurrently with development phases, and the location of this infrastructure would be identified in the final project design. As part of the project approval process, the project applicants of all project phases would coordinate with and meet the requirements of SMUD regarding the extension and locations of on-site infrastructure.

The proposed electrical-utility improvements would be required to comply with all existing City and SMUD requirements, and applicable requirements of the California Building Standards Code. Because SMUD would meet the electrical demands of the Reduced Hillside Development Alternative and provide new electrical infrastructure to the SPA, this **direct** impact is **less than significant**. The **indirect** physical impacts of constructing these facilities are addressed throughout this EIR/EIS in connection with discussions of the impacts of overall site development. ***[Greater]***

Mitigation Measure: No mitigation measures are required.

Off-Site Elements

Construction of the off-site freeway interchange improvements, the sewer force main, the detention basin in Sacramento County, and the two roadway connections into El Dorado Hills would not involve construction of new housing or development of new businesses. Therefore, there would be no increased demand for electricity and infrastructure, and **no direct** or **indirect** impacts would occur.

Mitigation Measure: No mitigation measures are required.

IMPACT 3A.16-9 Increased Demand for Natural Gas and Infrastructure. *Project implementation would increase the demand for natural gas and infrastructure and would include the extension of existing natural gas pipelines.*

On-Site Elements

NP

Under the No Project Alternative, development of up to 44 rural residences could occur under the existing Sacramento County agricultural zoning classification AG-80, and no off-site water facilities would be constructed. Construction of 44 individual rural residences within a 3,500-acre area would represent a very small increase in demand for natural gas. The proposed dwelling units would require 2.2 thousand cubic feet per hour (MCFH) of natural gas, which is approximately 816.1 MCFH less than the Proposed Project Alternative.

Individual property owners would be required to coordinate with PG&E to obtain natural gas service. Because the 44 individual rural residences that could be built under the No Project Alternative would result in minimal increases in demand for natural gas and because individual property owners would coordinate with PG&E regarding service, this **direct** impact is considered **less than significant**. **No indirect** impacts would occur. ***[Lesser]***

NCP

Buildout of the No USACE Permit Alternative would increase natural gas demands by 655.9 MCFH in the PG&E service area (Table 3A.16-5). This would be approximately 162.4 MCFH less than the Proposed Project Alternative.

Project implementation would require connection to the existing service lines with the ultimate configuration to be approved by PG&E. Two additional transmission mains and two natural gas regulator stations would also be

installed by PG&E to provide service to the project at full build-out. PG&E currently has capacity in its system to serve the SPA (Capitol Utilities Specialists 2009:6).

It is anticipated that 4-inch, 6-inch, and 8-inch transmission mains would be installed in major roadways throughout the SPA and 2-inch transmission mains would be installed in residential areas (Capitol Utilities Specialists 2009:7). The on-site service lines would be sized to meet the project demands, and public utility easements would be dedicated for all underground facilities. PG&E would extend lines and construct facilities to serve the SPA concurrently with development phases, and the location of this infrastructure would be identified in the final project design. As part of the project approval process, the project applicant(s) of all project phases would coordinate with and meet the requirements of PG&E regarding the extension and locations of on-site infrastructure.

Because PG&E is able to provide natural gas and associated infrastructure to the SPA under the No USACE Permit Alternative, and because the increase in demand for natural gas would not be substantial in relation to existing natural-gas consumption in PG&E's service area, this impact would be considered **direct** and **less than significant**. The **indirect** physical impacts of constructing these facilities are addressed throughout this EIR/EIS in connection with discussions of the impacts of overall site development. ***[Lesser]***

Mitigation Measure: No mitigation measures are required.

PP

Implementation of the Proposed Project Alternative would increase natural gas demand in the SPA. Natural gas service in Folsom is provided by PG&E through portions of PG&E's 46,000 miles of natural gas distribution pipelines. Buildout of the Proposed Project Alternative would increase natural gas demands by 818.3 MCFH in the PG&E service area (Table 3A.16-5).

PG&E currently has capacity in its system to serve the SPA (Capitol Utilities Specialists 2009:6). Existing natural gas transmission mains in the vicinity of the SPA include: a 6-inch transmission main on the west side of Prairie City Road north of U.S. 50, a 4-inch transmission main on Oak Avenue north of U.S. 50, a 6-inch transmission main at the intersection of East Bidwell Street and Iron Point Road, an 8-inch transmission main on Placerville Road north of U.S. 50, and a 6-inch transmission main at Stonebriar Road and White Rock Road. As described in detail in Chapter 2, "Alternatives," project implementation would require extensions of these existing service lines with the ultimate configuration to be approved by PG&E. Two additional transmission mains and two natural gas regulator stations would also be installed by PG&E to provide service to the project at full build-out.

It is anticipated that 4-inch, 6-inch, and 8-inch transmission mains would be installed in major roadways throughout the SPA and 2-inch transmission mains would be installed in residential areas (Capitol Utilities Specialists 2009:7). Public utility easements would be dedicated for all underground facilities. PG&E would extend lines and construct facilities to serve the SPA concurrently with development phases, and the location of this infrastructure would be identified in the final project design. As part of the project approval process, the project applicant(s) of all project phases would coordinate with and meet the requirements of PG&E regarding the extension and locations of on-site infrastructure.

Because PG&E is able to provide natural gas and associated infrastructure to the SPA under the Proposed Project Alternative, and because the increase in demand for natural gas would not be substantial in relation to existing natural-gas consumption in PG&E's service area, this impact would be considered **direct** and **less than significant**. The **indirect** physical impacts of constructing these facilities are addressed throughout this EIR/EIS in connection with discussions of the impacts of overall site development.

Mitigation Measure: No mitigation measures are required.

RIM

Buildout of the Resource Impact Minimization Alternative would increase natural gas demands by 694.2 MCFH in the PG&E service area (Table 3A.16-5). This would be approximately 124.1 MCFH less than the Proposed Project Alternative.

Project implementation would require connections to the existing service lines with the ultimate configuration to be approved by PG&E. Two additional transmission mains and two natural gas regulator stations would also be installed by PG&E to provide service to the project at full build-out. PG&E currently has capacity in its system to serve the SPA (Capitol Utilities Specialists 2009:6).

It is anticipated that 4-inch, 6-inch, and 8-inch transmission mains would be installed in major roadways throughout the SPA and 2-inch transmission mains would be installed in residential areas (Capitol Utilities Specialists 2009:7). The on-site service lines would be sized to meet the project demands, and public utility easements would be dedicated for all underground facilities. PG&E would extend lines and construct facilities to serve the SPA concurrently with development phases, and the location of this infrastructure would be identified in the final project design. As part of the project approval process, the project applicant(s) of all project phases would coordinate with and meet the requirements of PG&E regarding the extension and locations of on-site infrastructure.

Because PG&E is able to provide natural gas and associated infrastructure to the SPA under the Resource Impact Minimization Alternative, and because the increase in demand for natural gas would not be substantial in relation to existing natural-gas consumption in PG&E's service area, this impact would be considered **direct** and **less than significant**. The **indirect** physical impacts of constructing these facilities are addressed throughout this EIR/EIS in connection with discussions of the impacts of overall site development. ***[Lesser]***

Mitigation Measure: No mitigation measures are required.

CD

Buildout of the Centralized Development Alternative would increase natural gas demands by 837.7 MCFH in the PG&E service area (Table 3A.16-5). This would be approximately 19.4 MCFH more than the Proposed Project Alternative.

Project implementation would require connections to the existing service lines with the ultimate configuration to be approved by PG&E. Two additional transmission mains and two natural gas regulator stations would also be installed by PG&E to provide service to the project at full build-out. PG&E currently has capacity in its system to serve the SPA (Capitol Utilities Specialists 2009:6).

It is anticipated that 4-inch, 6-inch, and 8-inch transmission mains would be installed in major roadways throughout the SPA and 2-inch transmission mains would be installed in residential areas (Capitol Utilities Specialists 2009:7). The on-site service lines would be sized to meet the project demands, and public utility easements would be dedicated for all underground facilities. PG&E would extend lines and construct facilities to serve the SPA concurrently with development phases, and the location of this infrastructure would be identified in the final project design. As part of the project approval process, the project applicant(s) of all project phases would coordinate with and meet the requirements of PG&E regarding the extension and locations of on-site infrastructure.

Because PG&E is able to provide natural gas and associated infrastructure to the SPA under the Centralized Development Alternative, and because the increase in demand for natural gas would not be substantial in relation to existing natural-gas consumption in PG&E's service area, this impact would be considered **direct** and **less than**

significant. The **indirect** physical impacts of constructing these facilities are addressed throughout this EIR/EIS in connection with discussions of the impacts of overall site development. ***[Greater]***

Mitigation Measure: No mitigation measures are required.

RHD

Buildout of the Reduced Hillside Development Alternative would increase natural gas demands by 978.6 MCFH in the PG&E service area (Table 3A.16-5). This would be approximately 160.3 MCFH more than the Proposed Project Alternative.

Project implementation would require connections to the existing service lines with the ultimate configuration to be approved by PG&E. Two additional transmission mains and two natural gas regulator stations would also be installed by PG&E to provide service to the project at full build-out. PG&E currently has capacity in its system to serve the SPA (Capitol Utilities Specialists 2009:6).

It is anticipated that 4-inch, 6-inch, and 8-inch transmission mains would be installed in major roadways throughout the SPA and 2-inch transmission mains would be installed in residential areas (Capitol Utilities Specialists 2009:7). The on-site service lines would be sized to meet the project demands, and public utility easements would be dedicated for all underground facilities. PG&E would extend lines and construct facilities to serve the SPA concurrently with development phases, and the location of this infrastructure would be identified in the final project design. As part of the project approval process, the project applicant(s) of all project phases would coordinate with and meet the requirements of PG&E regarding the extension and locations of on-site infrastructure.

Because PG&E is able to provide natural gas and associated infrastructure to the SPA under the Reduced Hillside Development Alternative, and because the increase in demand for natural gas would not be substantial in relation to existing natural-gas consumption in PG&E's service area, this impact would be considered **direct** and **less than significant**. The **indirect** physical impacts of constructing these facilities are addressed throughout this EIR/EIS in connection with discussions of the impacts of overall site development. ***[Greater]***

Mitigation Measure: No mitigation measures are required.

Off-Site Elements

Construction of the off-site freeway interchange improvements, the sewer force main, the drainage basin in Sacramento County, and the two roadway connections into El Dorado Hills would not involve construction of new housing or development of new businesses. Therefore, there would be no increased demand for natural gas and infrastructure, and **no direct** or **indirect** impacts would occur.

Mitigation Measure: No mitigation measures are required.

IMPACT 3A.16-10 Increased Demand for Telecommunications Service and Infrastructure. *Project implementation would increase the demand for telecommunications service and infrastructure and would include the extension of existing telecommunication lines.*

On-Site Elements

NP

Under the No Project Alternative, development of up to 44 rural residences could occur under the existing Sacramento County agricultural zoning classification AG-80, and no off-site water facilities would be

constructed. Construction of 44 individual rural residences within a 3,500-acre area would represent a very small increase in demand for telecommunications service in the SPA. Individual property owners would be required to coordinate with AT&T or other service provider to obtain telecommunications service. Because the 44 individual rural residences that could be built under the No Project Alternative would result in minimal increases in communications service and because individual property owners would coordinate with the service provider(s) regarding service, this **direct** impact is considered **less than significant**. **No indirect** impacts would occur. ***[Lesser]***

NCP, PP, RIM, CD, RHD

AT&T would provide telecommunications service and associated infrastructure to the SPA. Currently, there are no existing telephone lines in the SPA. AT&T has existing underground telephone lines extending east from Prairie City Road along both side of White Rock Road. In addition, AT&T has existing overhead fiber optic cable that extends west from the El Dorado County line and parallels U.S. 50 on the south side, where it connects to SMUD's 12kV overhead transmission line.

The project would receive service from the Folsom Nimbus Wire Center and the El Dorado Wire Center. Residential service would be provided via fiber-optic cable and commercial and retail service would be provided via copper or fiber-optic cable (Capitol Utility Specialists 2009:7). New infrastructure would generally be placed within the rights-of-way of on-site streets. Extension of lines to serve the SPA would occur concurrently with development phases, and the location of this infrastructure would be identified in the final project design as part of the project approval process.

Because AT&T has capacity to provide service and because the project applicant(s) of all project phases would coordinate with AT&T regarding the extension and locations of on-site infrastructure, this **direct** impact is **less than significant**. The **indirect** physical impacts of constructing these facilities are addressed throughout this EIR/EIS in connection with discussions of the impacts of overall site development. ***[Similar]***

Mitigation Measure: No mitigation measures are required.

Off-Site Elements

Construction of the off-site freeway interchange improvements, the sewer force main, the detention basin in Sacramento County, and the two roadway connections into El Dorado Hills would not involve construction of new housing or development of new businesses. Therefore, there would be no increased demand for telecommunications service and infrastructure, and **no direct** or **indirect** impacts would occur.

Mitigation Measure: No mitigation measures are required.

IMPACT 3A.16-11 Increased Demand for Cable Television and Communications Service and Infrastructure. *Project implementation would increase the demand for cable television service and infrastructure and would include the extension of existing cable television lines.*

On-Site Elements

NP

Under the No Project Alternative, development of up to 44 rural residences could occur under the existing Sacramento County agricultural zoning classification AG-80, and no off-site water facilities would be constructed. Construction of 44 individual rural residences within a 3,500-acre area would represent a very small increase in demand for cable television service in the SPA. Individual property owners would be required to coordinate with the cable television and communications service provider to obtain cable television service.

Because the 44 individual rural residences that could be built under the No Project Alternative would result in minimal increases in cable television service and because individual property owners would coordinate with the cable television/communications service provider regarding service, this **direct** impact is considered **less than significant**. **No indirect** impacts would occur. ***[Lesser]***

NCP, PP, RIM, CD, RHD

Cable television, communications, and infrastructure would be provided by Comcast. Currently, there are no existing cable television facilities in the SPA. In the vicinity of the SPA, Comcast has existing facilities on Prairie City Road and along Iron Point Road north of U.S. 50. These facilities could be extended to serve the SPA. Another service option could include extending overhead on SMUD's existing 12kV overhead transmission line near U.S. 50 and Empire Ranch Road (Capitol Utility Specialists 2009:8).

Comcast would install a fiber-optic/coaxial cable hybrid system in the SPA. New infrastructure would generally be placed within the rights-of-way of on-site streets. Extension of lines to serve the SPA would occur concurrently with development phases, and the location of this infrastructure would be identified in the final project design as part of the project approval process. Because Comcast has the capacity to serve project development, and because the project applicant(s) of all project phases would coordinate with Comcast regarding the extension and locations of on-site infrastructure, this **direct** impact is considered **less than significant**. The **indirect** physical impacts of constructing these facilities are addressed throughout this EIR/EIS in connection with discussions of the impacts of overall site development. ***[Similar]***

Mitigation Measure: No mitigation measures are required.

Off-Site Elements

Construction of the off-site freeway interchange improvements, the sewer force main, the detention basin in Sacramento County, and the two roadway connections into El Dorado Hills would not involve construction of new housing or development of new businesses. Therefore, there would be no increased demand for cable television and communications service and infrastructure, and **no direct** or **indirect** impacts would occur.

Mitigation Measure: No mitigation measures are required.

IMPACT 3A.16-12 Increased Energy Demand. *Project implementation would increase energy consumption during construction and operation.*

On-Site Elements

NP

Under the No Project Alternative, development of up to 44 rural residences could occur under the existing Sacramento County agricultural zoning classification AG-80, and no off-site water facilities would be constructed. Construction of 44 individual rural residences within a 3,500-acre area would increase the consumption of energy during project-related construction activities. Energy in the form of fuel and electricity would be consumed during this period by construction vehicles and equipment, trucks delivering equipment and supplies, and construction worker commute trips. No unusual characteristics are expected that would necessitate the use of construction equipment that would be less energy-efficient than at comparable construction sites in other parts of the Sacramento region. The 44 individual rural residences that could be built under the No Project Alternative would result in minimal increases in demand for energy related to heating and cooling systems, lighting, appliances, and other miscellaneous energy requirements. Therefore, this **direct** impact is considered **less than significant**. **No indirect** impacts would occur. ***[Lesser]***

Project implementation would increase the consumption of energy for the duration of the project's construction and operation in the form of electricity, natural gas, and petroleum products. The primary energy demands during construction would be associated with construction vehicle fueling over the 19-year construction period. Energy in the form of fuel and electricity would be consumed during this period by construction vehicles and equipment operating on the site, trucks delivering equipment and supplies to the site, and construction workers driving to and from the site. There are no unusual project characteristics that would necessitate the use of construction equipment that would be less energy-efficient than at comparable construction sites in other parts of the Sacramento region. Therefore, it is expected that construction fuel consumption associated with the project would not be any more inefficient, wasteful, or unnecessary than at other construction sites in the region.

Energy would also be used for project operation related to heating and cooling systems, lighting, appliances, and other miscellaneous energy requirements. Design guidelines incorporated into the project identify energy conservation measures that would minimize inefficient energy usage and promote conservation of energy resources. These measures include:

- Incorporating site design measures that reduce heating and cooling needs by effectively orienting buildings toward southern exposures;
- Incorporating high-quality, energy efficient glazing to reduce heat loss and gain;
- Installing energy efficient appliances, windows, insulation; solar technology such as rooftop photovoltaic cell arrays; automatic lighting and thermostat features; and other available technologies to reduce energy demands; and
- Designing commercial and civic building and residential dwelling unit to allow for the possible installation of alternative energy technologies including active solar, wind, or other emerging technologies.

The project would comply with Building Energy Efficiency Standards included in Title 24 of the California Code of Regulations. Title 24 identifies specific energy efficiency requirements for building construction and systems operations that are intended to provide for efficient energy usage over the long-term.

Energy consumption would also be associated with vehicle trips resulting from residents and workers commuting on and off the SPA to jobs and commercial services. The project would provide residential land uses and a wide range of commercial services and employment opportunities for future residents in the SPA, reducing the need to travel outside the SPA. The design and placement of commercial and industrial land uses would result in the ability of employees to walk to convenience services and would provide nearby access to a system of walking trails and public transportation. An Air Quality Management Plan is currently being prepared that identifies measures that are intended to minimize air quality impacts associated with the project's vehicle trip generation. In addition to reducing the project's air quality impacts, these measures would also reduce the project's overall energy consumption.

Because the project would incorporate the design measures described above, comply with Building Energy Efficiency Standards (Title 24 of the California Code of Regulations), and implement an Air Quality Management Plan, the project would not be expected to cause the inefficient, wasteful or unnecessary consumption of energy, and this **direct** impact is considered **less than significant**. The **indirect** impacts associated with consumption of energy (e.g., construction of additional power generation plants and impacts associated therewith such as increased consumption of water at the plants, loss of biological habitat or cultural resources as result of power plant construction, etc.) are **uncertain** and are too far removed in place and time from the project to allow for a meaningful evaluation of impacts. Therefore, it would be too speculative to reach an impact conclusion regarding these indirect impacts. ***[Similar]***

Mitigation Measure: No mitigation measures are required.

Off-Site Elements

Construction of the off-site freeway interchange improvements, the sewer force main, the detention basin, and the two roadway connections into El Dorado Hills would increase the consumption of energy during project-related construction activities. Energy in the form of fuel and electricity would be consumed during this period by construction vehicles and equipment, trucks delivering equipment and supplies, and construction worker commute trips. There are no unusual project characteristics that would necessitate the use of construction equipment that would be less energy-efficient than at comparable construction sites in other parts of the Sacramento region. Therefore, it is expected that construction fuel consumption associated with the project-related off-site elements would not be any more inefficient, wasteful, or unnecessary than at other construction sites in the region.

The off-site freeway interchange improvements, the sewer force main, the detention basin, and the two roadway connections into El Dorado Hills would not involve construction of new housing or development of new businesses that would lead to an increase in residents or employees in the area and thus result in an increase in energy consumption. Therefore, there would be minimal amounts of increased energy demand during construction, and this **direct** impact is considered **less than significant**. **No indirect** impacts would occur.

Mitigation Measure: No mitigation measures are required.

3A.16.4 Residual Significant Impacts

Impacts associated with increased demand for SRCSD off-site wastewater collection and conveyance facilities; increased temporary and short-term and long-term generation of solid waste; and increased demands for electrical, natural gas, and ommunications service and infrastructure are considered less than significant. Therefore, there would be no residual significant impacts with respect to these issue areas. Implementation of mitigation measures contained in this section would reduce impacts associated with increased demand for on-site wastewater collection and conveyance facilities and the off-site force main to a less-than-significant level.

The project would increase demand for EID wastewater collection and conveyance facilities and the El Dorado Hills WWTP facilities. It is unknown if existing EID wastewater collection and conveyance facilities and El Dorado Hills WWTP facilities have the capacity to accommodate wastewater flows generated by project development, and project development could directly and indirectly contribute to the need for wastewater collection and conveyance facilities and treatment plant improvements. Therefore, the project could contribute to currently unknown but potentially significant environmental impacts associated with improvements to treatment plant facilities for which feasible mitigation may not be available to reduce impacts to a less-than-significant level, resulting in potentially significant and unavoidable residual impacts.

In addition, project implementation would increase demand for SRWTP facilities and would contribute to the need to expand the SRWTP; therefore, the project would contribute indirectly to one significant and unavoidable impact (related to air quality) identified in the 2020 Master Plan EIR. Therefore, a residual significant and unavoidable impact would occur.

This page intentionally left blank.

This section was prepared by RMC Water and Environment.

3B.16 UTILITIES AND SERVICE SYSTEMS – WATER

3B.16.1 AFFECTED ENVIRONMENT

This discussion places an emphasis on describing the affected environment for locations where physical environmental impacts would occur as a result of the construction and operation of the Off-site Water Facilities. For this issue area, the discussion is focused to Zone 4 of the "Water" Study Area.

POTABLE WATER DISTRIBUTION

Potable water supplies for the "Water" Study Area are provided by numerous public and private wholesale and retail water service providers. These public and private entities acquire water from surface and groundwater supplies, treat the water, and distribute the treated water to users. Within Sacramento County, there are 28 water purveyors that are responsible for treating and distributing local sources of surface water and groundwater to their respective customer bases. The Sacramento County Water Agency (SCWA) is responsible for providing water to all areas within the County not served by one of the 28 purveyors and serves areas in Zone 40, which overlaps portions of Zone 4 of the Off-site Water Facilities Study Area. The City is responsible for providing potable water to users within its city limits and would be responsible for supplying water to SPA.

New water supply infrastructure proposed as part of the Off-site Water Facilities would be constructed to serve areas within the SPA and, therefore, would be under the purview of the City. The new water system constructed in conjunction with the project would be separate from the City's system to the north of U.S. 50. The City's current total water demand (2006) for areas within the city limits is 27,392 acre-feet per year (AFY) and includes non-potable industrial water use at Aerojet. The 5,600 AFY of demand for the SPA is separate from the City's current demand and would be served by separate infrastructure. Water use within the current city limits is projected to experience a slight decrease by 2030 to 27,069 AFY based on average unit water demand factors applied to City land uses assumed in the City's 2005 Urban Water Management Plan (UWMP). This minor decrease in water use is largely attributed to a decrease in water use for construction activities. However, with the recent passage of Senate Bill (SB) 7 – Statewide Water Conservation, the estimates are likely to be further reduced depending on the City's established baseline usage.

Pursuant to an agreement between the City and Aerojet, industrial water demands for Aerojet will be met through either treated groundwater from Aerojet's Groundwater Extraction and Treatment (GET) Program or from a new source of water that Aerojet would pay the City to acquire and deliver. This agreement would effectively reduce projected potable water demands within the City by 2,731 AFY in 2030 to 24,338 AFY.

Central Valley Project

Water supplies that the City proposes to acquire from NCMWC are derived from the Central Valley Project (CVP), which is operated by U. S. Bureau of Reclamation (Reclamation). The CVP consists of 20 dams and reservoirs, 11 power plants, and 500 miles of major canals, as well as conduits, tunnels, and related facilities and are described in further detail in Section 3B. 9, "Hydrology and Water Quality – Water."

Water supplies managed as part of the CVP include approximately 9 million AFY (MAF) of water with annual deliveries averaging approximately 7 MAF of water for agricultural, urban, and wildlife uses. Of this total, approximately 600,000 AFY is allocated for municipal and industrial uses. In addition, approximately 800,000 AFY is allocated to fish and wildlife habitat and 410,000 AFY to state and Federal wildlife refuges and wetlands, pursuant to the Central Valley Project Improvement Act (CVPIA).

SANITARY SEWER COLLECTION

Sanitary sewer collection and treatment service within eastern portions of Sacramento County, including the City, is provided by the Sacramento Regional County Sanitation District (SRCSD) and its cooperating agency Sacramento Area Sewer District (SASD), formerly County Sanitation District No. 1 (CSD-1). The current SASD service area is approximately 286 square miles with more than 2,700 miles of sewer lines and serves over 950,000 people (CSD-1 2006). Zone 4 of the "Water" Study Area traverses the Aerojet Trunk Shed, which is served by the Folsom East and Aerojet Interceptors. These interceptors connect into the Bradshaw Interceptor, which conveys wastewater to the Sacramento Regional Wastewater Treatment Plant, west of Elk Grove, south of Sacramento.

The 2006 SASD Draft Master Plan Update (master plan) identifies the need for several new sewers in the vicinity of Zone 4 of the "Water" Study Area, including a new trunk line to serve the Aerojet property SRCSD is also proposing to upgrade the Mather Interceptor along Douglas Road and Sunrise Boulevard.

ELECTRICAL GENERATION AND TRANSMISSION

The Sacramento Municipal Utility District (SMUD) provides electrical service to Sacramento County. SMUD operates several 12- and 69-kilovolt (kV) overhead electrical lines along portions of Folsom Boulevard, Prairie City Road, Sunrise Boulevard, White Rock Road, Excelsior Road, Florin Road, and Douglas Road. In the eastern portion of the Off-site Water Facilities Study Area, SMUD operates a series of 230-kV electrical transmission lines that roughly parallel Grant Line Road and are part of the state's larger electrical transmission grid.

NATURAL GAS

Pacific Gas and Electric Company (PG&E) is the natural gas service provider for most of Sacramento County. Natural gas is delivered to Zone 4 of the "Water" Study Area through PG&E's existing network of underground natural gas pipelines. These pipelines are generally less than eight inches in diameter and housed in major roadways including Folsom Boulevard, Mather Boulevard, Sunrise Boulevard, Douglas Road, and Florin Road.

SOLID WASTE

Solid waste generated within Zone 4 of the "Water" Study Area is collected by the County or private carrier and transported to local transfer station(s) prior to disposal at Kiefer Landfill, which is located on 1,084 acres east of the intersection of Kiefer Boulevard and Grant Line Road. Kiefer Landfill has a permitted capacity to receive 10,800 tons of solid waste per day, and its estimated closure date is in 2064 (California Integrated Waste Management Board 2007). Kiefer Landfill is classified as a Class III municipal solid waste landfill facility and is permitted to accept general residential, commercial, and industrial refuse for disposal and has a total capacity of 117 million cubic yards – or 58 million tons. Currently, the landfill is operating below permitted capacity and will have capacity for the next 40 years based on current disposal rates (Sacramento County 2008b).

All non-recyclable solid waste generated during construction and operation of the Off-site Water Facilities is expected to ultimately be disposed of at Kiefer Landfill.

3B.16.2 REGULATORY FRAMEWORK

FEDERAL PLANS, POLICIES, REGULATIONS, AND LAWS

There are no Federal plans, policies, regulations, or laws related to utilities and service systems that apply to the Off-site Water Facility Alternatives under consideration.

STATE PLANS, POLICIES, REGULATIONS, AND LAWS

The following state plans, policies, regulations, and laws related to public utilities are relevant to the Off-site Water Facilities alternatives, and are described in detail in Section 3A.16, "Utilities and Service Systems – Land:"

- California Integrated Waste Management Act
- California Public Utilities Commission Decision 95-08-038
- California Building Energy Efficiency Standards

California Green Building Standards

The draft 2010 California Green Building Standards (CALGREEN) Code was unanimously adopted by the California Building Standards Commission and requires all new buildings in the state to be more energy efficient and environmentally responsible. CALGREEN will require that every new building constructed in California reduce water consumption by 20%, divert 50% of construction waste from landfills and install low pollutant-emitting materials. It also requires separate water meters for nonresidential buildings' indoor and outdoor water use, with a requirement for moisture-sensing irrigation systems for larger landscape projects and mandatory inspections of energy systems (e.g., heat furnace, air conditioner and mechanical equipment) for nonresidential buildings over 10,000 square feet to ensure that all are working at their maximum capacity and according to their design efficiencies. CALGREEN is scheduled to become effective on January 1, 2011, the current draft is provided for informational purposes only pending publication.

Senate Bill 7, Statewide Water Conservation

The goal of Senate Bill (SB) 7 is to require state to achieve a 20% reduction in urban per capita water use in California by December 31, 2020. SB 7 also includes an incremental goal of reducing per capita water use by 10% by December 31, 2015. The supplier must use one of the following methods for developing its urban water use target:

- 80% of the baseline per capita daily water use.
- Per capita daily water use that is estimated using the sum of an indoor residential use of 55 gallons per capital per day (gpcd) for landscape irrigated through dedicated or residential meters or connections, the model water efficient landscaping ordinance water efficiency equivalent + CII use equivalent to 90% of baseline CII water use by 2020.
- 95% of applicable state hydrologic region target as set forth in state's draft 20x2020 Water Conservation Plan.
- Other methods identified and developed by the California Department of Water Resources (DWR) through a public process and reported to the legislature no later than December 31, 2010.

REGIONAL AND LOCAL PLANS, POLICIES, REGULATIONS, AND LAWS

Water Supply

The Sacramento County General Plan Public Facilities Element encourages new development to be served by existing public water systems, either by annexation to an existing water purveyor's service area or by extension or creation of a benefit zone of the SCWA (Sacramento County 1993). Objectives of the General Plan policies include minimizing impacts on in-stream water flows in the Sacramento and American Rivers and consolidating water service under existing public water systems.

Pursuant to California Water Code Section 10610, the City of Folsom adopted its 2005 UWMP in April 2006 (City of Folsom 2006). The UWMP provides information on existing and projected water supplies, assesses the

reliability of these supplies given a range of hydrologic conditions, identifies the various customer types and their existing and projected demands, and provides a variety of water management strategies to reduce demand and conserve water resources. Although the "Water" Study Area does not include the city limits, it does include portions of the City's water service area south of Folsom Boulevard. Additionally, the Off-site Water Facilities water supplies and demands from the Folsom South of 50 SPA were not considered in the 2005 UWMP.

The City signed the January 2000 Water Forum Agreement (WFA), a nonbinding memorandum of understanding (MOU) with two coequal objectives: 1) to provide a reliable and safe water supply for the region's economic health and planned development to the year 2030; and 2) to preserve the fishery, wildlife, recreational, and aesthetic values of the Lower American River. The MOU includes a Purveyor Specific Agreement for the City that identifies actions for achieving reductions in surface water diversion in dry years.

Solid Waste

The California Integrated Waste Management Act (CIWMA) of 1989, also commonly known as Assembly Bill (AB) 939, requires local agencies to implement source reduction, recycling, and composting in efforts to divert 50% of their solid waste from landfills by the end of 2000. This act further required every city and county in California to prepare a Source Reduction and Recycling Element, a report describing (1) the chief characteristics of each jurisdiction's waste, (2) existing waste diversion programs and rates of waste diversion, and (3) the new or expanded programs the jurisdiction intends to implement to achieve the mandated rates of diversion. Waste diversion rates within the City have ranged from 27 to 32% since 2003 (CIWMB 2008).

3B.16.3 Environmental Consequences and Mitigation Measures

Thresholds of Significance

The thresholds for determining the significance of impacts for this analysis are based on the environmental checklist in Appendix G of the State CEQA Guidelines. These thresholds also encompass the factors taken into account under NEPA to determine the significance of an action in terms of its context and the intensity of its impacts. For the purposes of this analysis, an impact to existing and proposed utilities and service systems would be significant if the Off-site Water Facilities would:

- exceed wastewater treatment requirements of the applicable Regional Water Quality Control Board;
- require or result in the construction of new water, drainage, or wastewater treatment facilities or expansion of existing facilities, the construction of which could cause significant environmental effects;
- require new or expanded water supply entitlements available to serve the project;
- result in a determination by the wastewater treatment provider, which serves or may serve the project, that it has inadequate capacity to serve the project's projected demand in addition to the provider's existing commitments;
- result in substantial disruption(s) to existing public and/or provide utility service providers and supporting infrastructure;
- be served by a landfill with insufficient permitted capacity to accommodate the project's solid waste disposal needs; or
- not comply with Federal, state, and local statutes and regulations related to solid waste.

Energy Efficiency

In accordance with criteria adopted from Appendix F of the State CEQA Guidelines, and encompassing the factors taken into account under NEPA to determine the significance of an action in terms of its context and the intensity of its impacts, Off-site Water Facilities-related impacts to energy resources are considered to be potentially significant if the Off-site Water Facilities would:

- Result in wasteful, inefficient, and unnecessary consumption of energy during the project construction, operation, maintenance, and/or removal that cannot be feasibly mitigated; or
- Preempt future energy development or future energy conservation.

ANALYSIS METHODOLOGY

This analysis provides an evaluation of the potential impacts to existing utilities and service systems based on actions outlined in Chapter 2, "Alternatives." Findings and conclusions presented in the impact analysis are based on foreseeable changes to existing conditions as result of the Off-site Water Facilities and the significance criteria presented above. Given that implement of the Off-site Water Facility Alternatives involves the construction of water supply conveyance and treatment facilities, the "B," or "Water" sections of Chapter 3 provide a comprehensive analysis of the range of potential environmental effects of the Off-site Water Facility Alternatives currently under consideration.

ISSUES NOT DISCUSSED FURTHER IN THIS EIR/EIS

The Off-site Water Facilities as described in Chapter 2, "Alternatives" include the construction of new water supply conveyance and treatment infrastructure. The specific impacts associated with construction, such as air quality degradation and noise generation, as well as other construction-related impacts are addressed in each technical section throughout the "B," or "Water" sections of Chapter 3 and Chapter 4, "Other Statutory Requirements."

IMPACT ANALYSIS

Impacts that would occur under each of the Off-site Water Facility Alternatives are identified as follows:

NCP (No USACE Permit Alternative)

PA (Proposed Off-site Water Facility Alternative)

1 (Off-site Water Facility Alternative 1 – Raw Water Conveyance – Gerber/Grant Line Road Alignment and White Rock WTP)

1A (Off-site Water Facility Alternative 1A Raw Water Conveyance – Gerber/Grant Line Road Alignment Variation and White Rock WTP)

2 (Off-site Water Facility Alternative 2 Treated Water Conveyance – Douglas Road Alignment and Vineyard SWTP)

2A (Off-site Water Facility Alternative 2A Treated Water Conveyance – Excelsior Road Alignment Variation and Vineyard SWTP)

2B (Off-site Water Facility Alternative 2B Treated Water Conveyance – North Douglas Tanks Variation and Vineyard SWTP)

3 (Off-site Water Facility Alternative 3 Raw Water Conveyance – Excelsior Road Alignment and White Rock WTP)

3A (Off-site Water Facility Alternative 3A Raw Water Conveyance – Excelsior Road Alignment Variation and White Rock WTP)

4 (Off-site Water Facility Alternative 4 Raw Water Conveyance – Easton Valley Parkway Alignment and Folsom Boulevard WTP)

4A (Off-site Water Facility Alternative 4A Raw Water Conveyance – Easton Valley Parkway Alignment Variation and Folsom Boulevard WTP).

The impacts for each alternative are compared relative to the PA at the end of each impact conclusion (i.e., similar, greater, lesser).

IMPACT 3B.16-1 Generation of Wastewater. *The operation of the Off-site Water Facility Alternatives would generate wastewater that would require off-site conveyance and treatment.*

NCP, PA, 1, 1A, 2, 2A, 2B, 3, 3A, 4, and 4A

Implementation of the Off-site Water Facility Alternatives would not directly or indirectly exceed wastewater treatment requirements of the Central Valley RWQCB, or exceed the capacity of the SRCSD's Folsom Interceptor. The Off-site Water Facility Alternatives would involve the use of surface water supplies, which currently meets strict drinking water standards, and therefore, the Off-site Water Facilities would not involve the use of a water supply that could otherwise contribute to a violation of any water quality standards or WDRs for SRCSD. Potential indirect effects to SRCSD's ability to meet future WDRs and water quality standards as a consequence of growth within the SPA is broadly evaluated at a programmatic level in Section 3A.16.3 and in the context of growth-inducing impacts in Chapter 4, "Other Statutory Requirements."

Once operational, the WTP would generate a very minor quantities of wastewater and as described and analyzed in more detail in Section 3B.9, "Hydrology and Water Quality – Water," all solids generated from treatment-related operations would be hauled off-site and not into the sanitary sewer system. Further and in the context of the SPA and the amount of sanitary sewer conveyance and treatment capacity required to service the SPA at full buildout, the Off-site Water Facilities WTP's additional contribution would be negligible and ultimate connection would need to occur through the trunk system constructed for the SPA. For this reason, the Off-site Water Facility Alternatives are not expected to interfere with SRCSD's existing commitments for wastewater service and the **direct** and **indirect** impacts to existing and planned wastewater infrastructure are expected to be **less than significant**. This issue is discussed further in the context of growth-inducing impacts in Chapter 4, "Other Statutory Requirements." ***[Similar]***

The Off-site Water Facilities constructed under these alternative would connect with existing or planned sanitary sewer infrastructure and would not require additional off-site wastewater conveyance or treatment infrastructure. Therefore, no additional off-site impacts beyond those identified in "B" or "Water" sections of Chapter 3 for all the Off-site Water Facility Alternative would occur. Because the alternatives would connect with existing or planned sanitary sewer infrastructure, the **direct** and **indirect** impacts would be **less than significant**. ***[Similar]***

Mitigation Measure: No mitigation measures are required.

IMPACT 3B.16-2 Changes in Operation of the Central Valley Project Water Supply Entitlement. *The operation of the Off-site Water Facility Alternatives would not infringe upon the water rights of other legal users of water.*

NCP, PA, 1, 1A, 2, 2A, 2B, 3, 3A, 4, and 4A

The Off-site Water Facility Alternatives would involve a slight change in operation of the CVP service system to deliver water to City through the Freeport Project service area instead of NCMWC. The assigned CVP water entitlement would continue to be stored in upstream reservoirs, but would be delivered under an M&I schedule as opposed to the existing agricultural delivery schedule. Instead of diverting water at NCMWC's service area, the Off-site Water Facilities would divert CVP water at the Freeport Project intake approximately 20 miles downstream.

As described in more detail in Section 3B.9, "Hydrology and Water Quality – Water," and shown in Table 3B.9-3, the change in the current delivery schedule would result in a minor increase in the diversion of surface water during winter and spring months, however, this increase equates to less than 0.04% in relation to the minimum flows at Freeport during these months. This increase would be offset by a more substantial decrease in diversions during the months of July and August, which is the height of the irrigation season or when demands for surface water are at their highest. Notwithstanding this change in the CVP delivery schedule, the remaining changes to flows within the Sacramento River as a result of the Off-site Water Facilities area are largely attributed to the lower quantity of return water that makes it back to the river following use within the SPA as compared to the NCMWC. However, given that this minor increase would occur during periods when higher flows are present within the Sacramento River, the operation of the Off-site Water Facilities would not significantly affect other diversions within the Sacramento River and Delta, including SWP and CVP water exports. These **direct** and **indirect** impacts are considered **less than significant**. ***[Similar]***

As described in Chapter 2, "Alternatives," all build-out alternatives for the SPA would require less than 5,600 AFY to supply both potable and non-potable water demands during normal and dry years. As provided in Table 3B.9-3, the purchasing and acquisition of 8,000 AFY of CVP water from NCMWC would be sufficient to accommodate demands from all uses within the SPA, including demands during dry years. The conclusions contained in the Water Supply Assessment in Appendix M further confirm these findings and provide a level of conservation that could foreseeable be less than required in the future with the passage of SB 7 in 2009. The CVP supply in question has been delivered for over the past 50 years and given that the Freeport Project diversion is an existing diversion facility north of the Delta, this supply is not subject to the controversy currently centered around conveyance through and diversion of CVP water supplies from the Delta. Additionally and as support in Chapter 2, "Alternatives," the City has entered into preliminary MOUs with the necessary parties (e.g., SCWA) required to facilitate wheeling of the secured CVP supplies. Based on these considerations, the CVP supply and conveyance agreements are considered reliable and sufficient to meet all water demands generated from uses within the SPA. Based on these circumstances, these **direct** and **indirect** impacts are considered **less than significant**. ***[Similar]***

Mitigation Measure: No mitigation measures are required.

IMPACT 3B.16-3 Potential Disruption to Existing Utilities and Infrastructure. *Construction of the Off-site Water Facilities has the potential to disrupt existing public and private utilities and infrastructure.*

NCP, PA, 1, 1A, 2, 2A, 2B, 3, 3A, 4, and 4A

Several municipal and private utilities, including those owned and operated by SCWA, PG&E, SMUD, SRCSD, and CSD-1, have existing underground utilities and future projects proposed within Zone 4 of the Off-site Water Facilities Study Area. Construction activities associated with the Off-site Water Facility Alternatives could

potentially result in a disturbance of existing utilities or conflict with planned utility projects. Without a clear understanding of the location and placement of existing utilities, including existing sanitary sewer, natural gas, and potable water lines, Off-site Water Facilities-related trenching operations could come into contact with such utilities thereby disrupting service and potentially endangering construction workers. This **direct** impact is considered **potentially significant**. **Indirect** impacts from potential service disruptions would also be **potentially significant** if the duration of the outage extend for longer than few days. ***[Similar]***

Potential impacts to SCWA as a result of a reduced conveyance capacity within the Freeport Project would be minimized through the compliance with the conditions contained within the MOU between the City and SCWA as provided in Appendix M-III. Even though the MOU is a non-binding agreement, without it the Off-site Water Facility Alternatives could not occur. For this reason, **direct** and **indirect** operational impacts to SCWA would be **less than significant**. ***[Similar]***

Mitigation Measure 3B.16-3a: Minimize Utility Conflicts by Implementing an Underground Services Alert.

Underground utilities and service connections shall be identified prior to commencing any excavation work through the implementation of an Underground Services Alert (USA). The exact utility locations will be determined by hand-excavated test pits dug at locations determined and approved by the construction manager (also referred to as "pot-holing"). Temporary disruption of service may be required to allow for construction. No service on such lines would be disrupted until prior approval is received from the construction manager and the service provider.

Implementation: City of Folsom Utilities Department

Timing: Prior to construction of all Off-site Water Facilities

Enforcement: Public and Private Utilities, where applicable, including: Sacramento County Sanitation District, Pacific Gas and Electric, Sacramento Municipal Utility District, City of Folsom Public Works Department, Sacramento County Department of Water Resources, Sacramento County Water Agency, City of Rancho Cordova Public Works Department, Sacramento County Roads and Airports, and Aerojet Corporation.

Mitigation Measure 3B.16-3b: Coordinate with Utility Providers and Implement Appropriate Installation Methods to Minimize Potential Utility Service Disruptions.

Prior to installation, the City shall consult with SCWA, SRCSD, CSD-1, and PG&E to determine proper installation methods and final design criteria to minimize the potential for disruptions to existing and planned utilities.

Implementation: City of Folsom Utilities Department

Timing: Prior to construction of all Off-site Water Facilities

Enforcement: Public and Private Utilities, where applicable, including: Sacramento County Sanitation District, Pacific Gas and Electric, Sacramento Municipal Utility District, City of Folsom Public Works Department, Sacramento County Department of Water Resources, Sacramento County Water Agency, City of Rancho Cordova Public Works Department, Sacramento County Roads and Airports, Golden State Water Company and Aerojet Corporation.

Implementation of Mitigation Measures 3B.16-3a and 3B.16-3b would reduce potentially significant impacts under Alternatives PA, 1, 1A, 2, 2A, 2B, 3, 3A, 4, and 4A to a **less-than-significant** level by requiring consultation with the respective utility operators to determine potential utility conflicts.

IMPACT 3B.16-4 Increased Generation of Solid Waste. *Construction and operation of the Off-site Water Facilities would generate solid waste, which could impact the City's ability to comply with solid waste diversion requirements of the state.*

NCP, PA, 1, 1A, 2, 2A, 2B, 3, 3A, 4, and 4A

Construction of the Off-site Water Facilities would generate substantial amounts of construction debris, especially during the construction of the structural foundations, and to a lesser extent, during the installation of the conveyance pipeline. Some materials excavated during Off-site Water Facilities trenching would be used as fill materials at the WTP or storage tanks sites(s). Once collected, non-reusable solid wastes generated during construction (including recyclable materials) would be taken to the nearest Materials Recovery Facility/transfer station with non-recyclables being transferred to the Class III, Kiefer Landfill.

As provided in the affected environment discussion, Kiefer Landfill has 40 years of remaining capacity based on current disposal rates. The quantity of solid wastes generated during WTP operations would be minor, consisting primarily of domestic-type wastes, and managed on-site by the City. Sludge-handling following dewatering and drying would be land-applied as agricultural fertilizer to willing buyers or hauled to the Kiefer Landfill. Neither the total annual solid waste generated by the Off-site Water Facilities, nor the degree of increase from existing conditions, would be considered a significant level that would potentially exceed landfill capacity.

The City as part of the operation of the Off-site Water Facilities would, to the extent applicable, participate in existing recycling and waste diversion programs. The Off-site Water Facilities would ensure suitable storage locations and containers for recyclable materials in or around the project buildings and public outdoor spaces, and the design, location, and maintenance of recycling collection and storage areas. Therefore, the contribution of the Off-site Water Facilities to the overall waste stream in and of itself is not considered significant, and with continued participation and adherence to these programs, implementation of the Off-site Water Facilities would not require or result in new or expanded landfill facilities or impede the City's ability to meet mandated waste diversion requirements. These **direct** and **indirect** impacts are considered **less than significant**. ***[Similar]***

Mitigation Measure: No mitigation measures are required.

IMPACT 3B.16-5 Potential Inefficient Energy Consumption. *Construction and operation of the Off-site Water Facilities could result in the inefficient consumption of energy thereby adversely affecting current and future energy conservation efforts.*

NCP, PA 1, 1A, 3, 3A, 4, and 4A

During construction, the Off-site Water Facility Alternatives would consume energy in two general forms: 1) the fuel energy consumed by construction vehicles and equipment; and 2) bound energy used in the manufacturing and processing of construction materials such as steel, concrete, pipes, lumber, and glass. Energy in the form of fuels used for construction vehicles and other equipment would be used during site clearing, grading, and construction. Such fuel energy use would be temporary and not represent a significant or permanent commitment to the use of energy. In addition, given high fuel prices, contractors have a strong financial incentive to avoid wasteful, inefficient, and unnecessary consumption of energy during construction.

Though Off-site Water Facilities construction is not anticipated to occur until 2010, substantial reductions in energy inputs for construction materials can be achieved by selecting building and construction materials composed of recycled materials, which require substantially less energy to produce than from non-recycled materials. Examples of recycled building materials include the use of: 1) recycled nylon in interior carpeting; 2) recycled plastic for moldings and interior finishes; 3) fly ash in concrete; and 4) recycled rubber in asphalt. The extent to which recycled materials would be used during construction of the Off-site Water Facilities has not yet been determined.

There would also be some non-renewable petroleum-based fuel savings resulting from Mitigation Measures 3B.2-1a and 3B.2-1b in Section 3B.2, "Air Quality – Water," which would prevent the unnecessary idling of vehicles and equipment and require that vehicles and equipment be properly maintained. In addition, a Solid Waste Diversion and Recycling Plan (or such other documentation to the satisfaction of the City) would be required to be in place that demonstrates the diversion from landfills and recycling of all non-hazardous, salvageable, and re-useable wood, metal, plastic, and paper products during construction and demolition activities. This would minimize the waste of bound energy used in the original manufacturing and processing of construction materials. Taken together, these Off-site Water Facilities characteristics and mitigation measures demonstrate that the proposed Off-site Water Facilities would assist the region in increasing its reliance on renewable, non-petroleum-based energy resources. This **direct** impact would be **potentially significant**. ***[Similar]***

Off-Site Water Facilities Operations

The Off-site Water Facilities WTP, booster pump station, and distribution infrastructure would increase demands for electricity within the "Water" Study Area. Based on energy consumption calculations used to quantify greenhouse gas emissions (GHGs) and provided in Appendix M, operations of the collective Off-site Water Facilities at build-out within the SPA could require upwards of 20.7 megawatts hours (MWh) annually. This increase in energy use would represent a new demand for electricity. With the implementation of measures recommended in Mitigation Measure 3B.4-1b to minimize the generation of GHGs, these measures would also promote energy efficiency consistent with standards contained in Title 24 of the California Code of Regulations (2007) and CALGREEN, aimed at the incorporation of energy-conserving design and construction.

Existing electrical distribution infrastructure exists adjacent each of the WTP sites, and any improvements and extensions required to accommodate the Off-site Water Facilities would be limited to on-site locations and performed in consultation with SMUD prior to installation.

Because the Off-site Water Facilities would not result in an extended disruption in service provided by a utility and would be operated in the most efficient manner possible, the **potentially significant direct** impact generated by additional power supply requirements and would be reduced to a less-than-significant level. ***[Similar]***

Mitigation Measures: Implement Mitigation Measures 3B.4-1a and 3B.4-1b.

2, 2A, and 2B

The impact discussion for the above alternatives, as it relates to construction-related energy consumption, would generally apply to Alternatives 2, 2A, and 2B. However, given that these alternatives further integrate the Off-site Water Facilities components with existing water supply infrastructure operated by SCWA, additional efficiencies would be expected in terms of the reduced length of the conveyance alignment, especially for Off-site Water Facility Alternative 2B, and a corresponding reduction in the need for the manufacturing and processing of construction materials such as steel, concrete, pipes, and lumber for the WTP. This **direct** impact would be **less than significant**. [***[Lesser]***

Off-site Water Facility Alternatives 2, 2A, and 2B would integrate water treatment operations into SCWA's Vineyard SWTP thereby potentially achieving additional energy efficiencies by requiring the Vineyard SWTP to

operate closer to its design capacity. However, the new power requirements generated under Alternative 2B, the most-energy efficient Off-site Water Facility Alternatives, could still exceed 7,000 MWh per year. This **direct** impact is **potentially significant**. ***[Lesser]***

Mitigation Measures: Implement Mitigation Measures 3B.4-1a and 3B.4-1b.

With the application of Mitigation Measures 3B.4-1a and 3B.4-1b, the City's energy usage during construction and operation of the Off-site Water Facilities would be minimized to the maximum extent feasible and therefore the impact would be reduced to a **less-than-significant** level.

3B.16.4 RESIDUAL SIGNIFICANT IMPACTS

Construction of the Off-site Water Facility Alternatives would involve activities that could directly impact existing utility services; however, with mitigation implementation, the identified impacts would reduced to less-than-significant levels through proper notification and coordination. Operational impacts would be minimized and addressed through interagency MOUs and therefore, are not expected to result in any residual significant unavoidable impacts to public and private utility and service systems.

Water supplies proposed for use within the SPA have a demonstrated reliability over the historic record and would not lead to further limits on other existing or potential water right users. Based on these circumstances, the proposed CVP water supply would be sufficient to accommodate projected water demands and, therefore, no residual, significant and unavoidable impacts would occur.

Construction and operation of the Off-site Water Facilities would be conditioned to be as energy efficient as feasible and would be required to maximize recycling opportunities to minimize the quantity of solid waste transported to existing landfills. Based on these circumstances, no residential, significant and unavoidable impacts related to energy use would occur.

This section was prepared by RMC Water and Environment.

3B.17 GROUNDWATER RESOURCES – WATER

3B.17.1 AFFECTED ENVIRONMENT

The following sections describe the groundwater basin and associated subbasins that underlie the Off-Site Water Facilities Study Area. Exhibit 3B.17-1 illustrates the geographic extent of these subbasins in relation to the Off-Site Water Facilities Study Area. These subbasins are located within the Sacramento Valley Groundwater Basin and are described in detail below.

SACRAMENTO VALLEY GROUNDWATER BASIN

The Sacramento Valley Groundwater Basin is the major groundwater basin in the Sacramento River Hydrologic Region and is considered a single aquifer system (Domagalski and Brown, 1996). The storage capacity of the Sacramento Valley Groundwater Basin is estimated at approximately 114 million AF beginning at depths of 20 to 60 feet below the land surface. Groundwater provides about 31% of the water supply for urban and agricultural uses in the region. This groundwater basin is comprised of 18 groundwater smaller subbasins, which include the South and North American Subbasins. These two groundwater subbasins underlie the Off-site Water Facilities Study Area and are described further below.

NORTH AMERICAN GROUNDWATER SUBBASIN

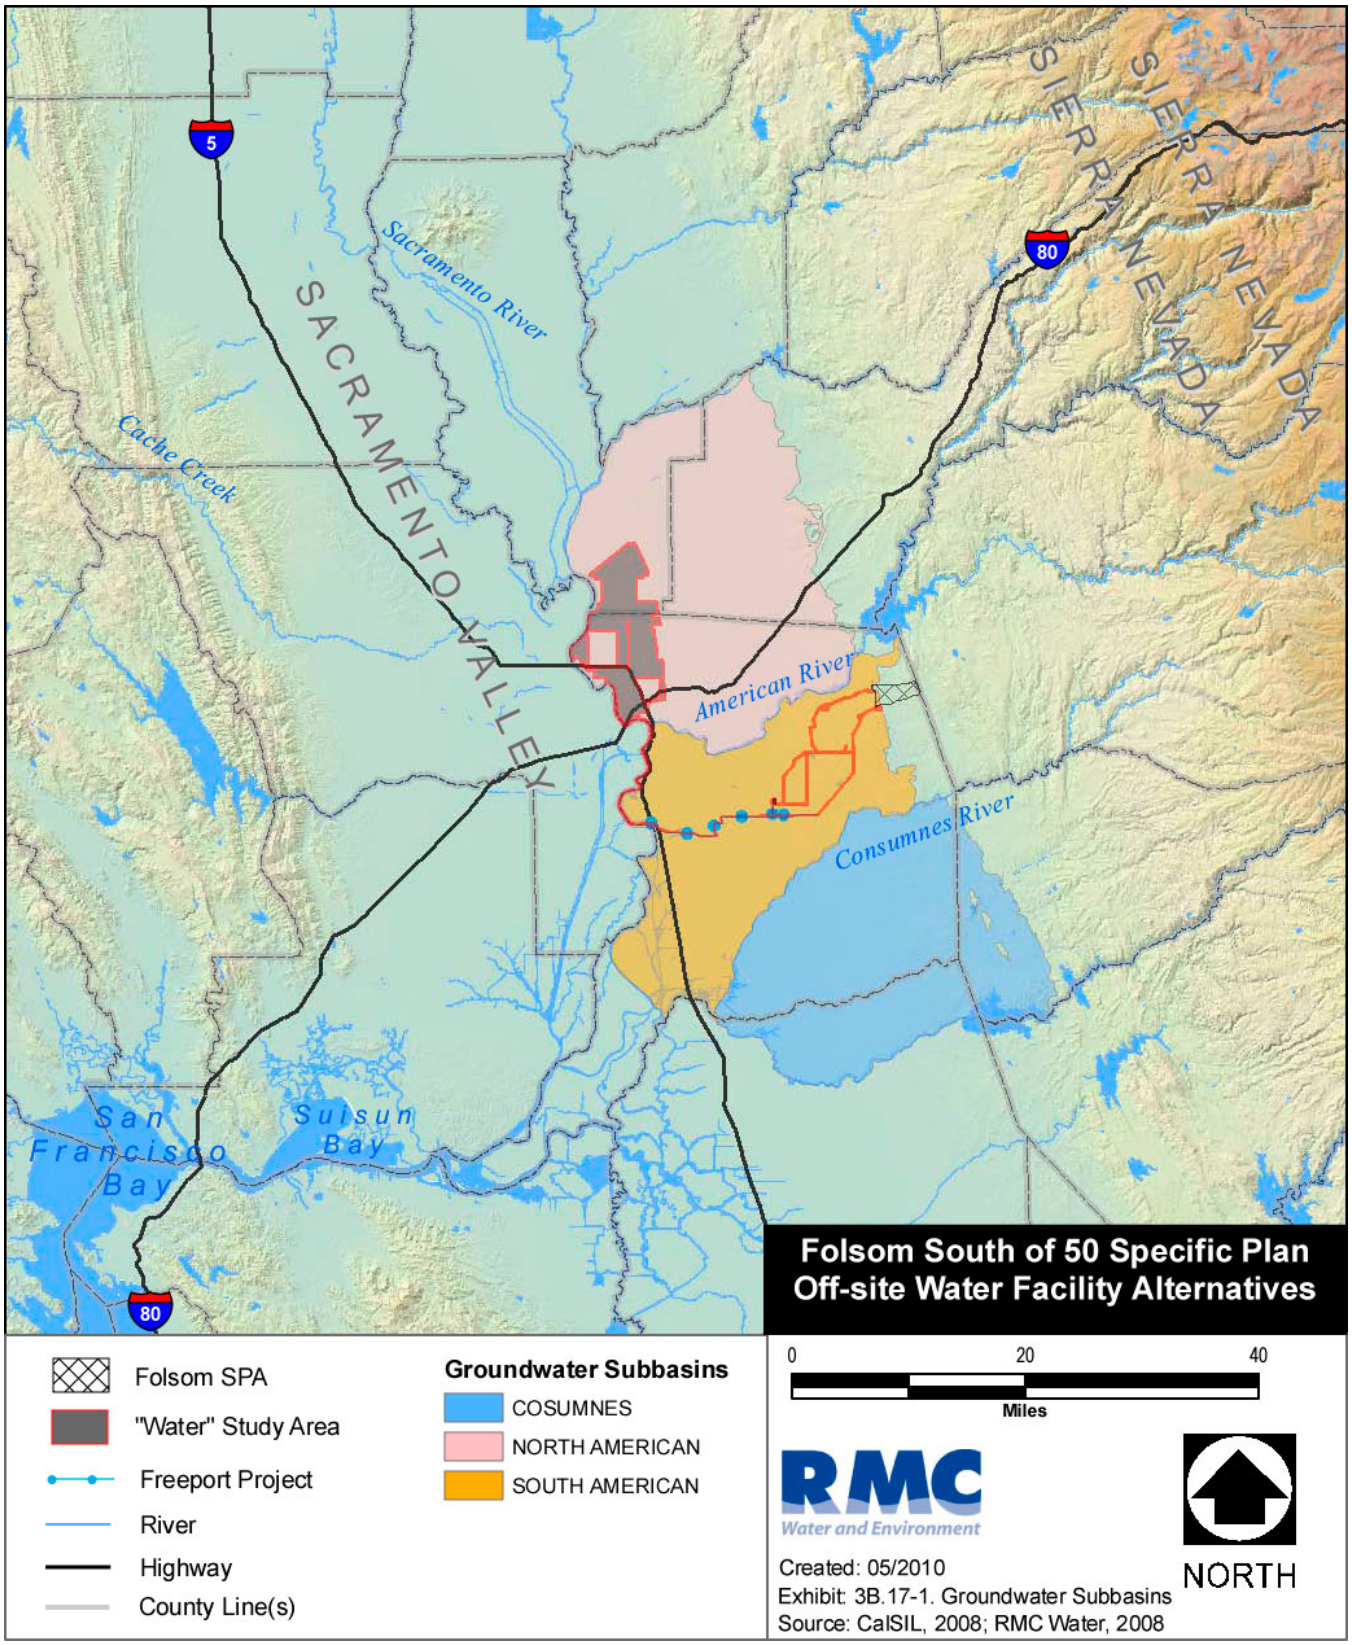
As shown in Exhibit 3B.17-1, the Natomas Central Mutual Water Company (NCMWC) or Zone 1 of the Off-site Water Facilities Study Area overlies the southwestern portion of the North American Groundwater Subbasin, which encompasses approximately 548 square miles in the east-central portion of the Sacramento Valley Groundwater Basin (California Department of Water Resources [DWR], 2006). The Bear River is its northern boundary, the Feather River is its western boundary, and the Sacramento River and American Rivers are its southern boundary. The eastern boundary is a north-south line extending from the Bear River south to Folsom Lake and represents the approximate edge of the alluvial deposits, where little or no groundwater flows into or out of the groundwater basin from the rock of the Sierra Nevada (DWR, 1997; DWR, 2006).

The estimated storage capacity for the North American Subbasin is approximately 4,900,000 acre-feet (AF) (DWR, 2006). The Water Forum Agreement (WFA) establishes a long-term average sustainable yield of 131,000 AFY for portions of the North American Subbasin underlying Sacramento County. Within this portion of the Subbasin, groundwater is typically used as a supplemental supply to surface water. In wet/average years[1], the need for supplemental groundwater supplies is estimated to be approximately 49,190 AF per year (AFY), which is below the 131,000 AFY long-term sustainable yield estimate cited in the WFA. The need for supplemental groundwater supplies during drier years is estimated to range from 102,110 to 132,520 AFY with the driest exceeding the 131,000 AFY long-term sustainable yield (Sacramento Groundwater Authority [SGA], 2003).

SOUTH AMERICAN GROUNDWATER SUBBASIN

Portions of the Off-site Water Facilities Study Area, more specially Zones 3 and 4 overlie the South American Groundwater Subbasin, also synonymous with the Central Sacramento County Groundwater Basin, which encompasses approximately 388 square miles in the east-central portion of the Sacramento Valley Groundwater

[1] Under the WFA a wet year is defined as those years when the projected March through November unimpaired inflow into Folsom Reservoir is equal to or greater 1,600,000 AF. A normal year is defined as more than 950,000 AF. Drier years are defined as those years when the projected March through November unimpaired inflow into Folsom Reservoir is less than 950,000 AF but equal to or greater than 400,000 AF.



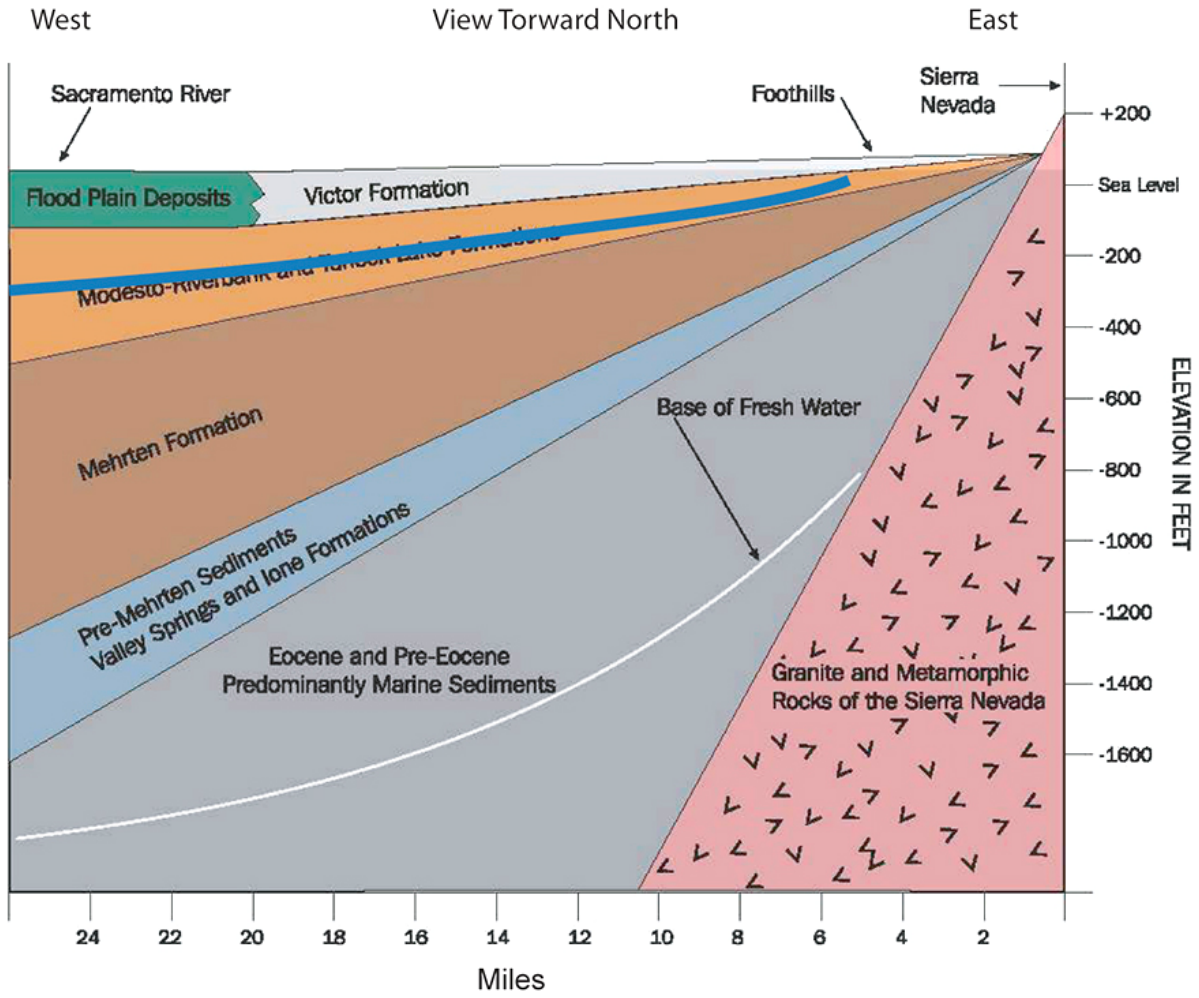
Local Groundwater Subbasins **Exhibit 3B-17-1**

Basin, south of the American River. This subbasin is bounded on the east by the Sierra Nevada foothills, on the west by the Sacramento River, on the north by the American River, and on the south by the Cosumnes and Mokelumne Rivers (see Exhibit 3B.17-1).

Hydrogeology

The South American Subbasin aquifer system is comprised of continental deposits of Late Tertiary to Quaternary age. These deposits include younger alluvium (consisting of flood basin deposits, dredge tailings and Holocene stream channel deposits), older alluvium, and Miocene/Pliocene volcanics (DWR, 2003). The cumulative thickness of these deposits increases from a few hundred feet near the Sierra Nevada foothills on the east to over 2,500 feet along the western margin of the subbasin.

Similar to the North American Subbasin, the South American Subbasin is characterized by two major water-bearing zones. The shallow aquifer zone occurs within the Laguna and/or Modesto formations and extends to 200-300 feet below the ground surface. The shallow aquifer is typically used for private domestic wells requiring no treatment unless high arsenic values are encountered. Older municipal and all domestic wells have been constructed in the shallow aquifer. Exhibit 3B.17-2 illustrates a generalized geologic cross-section for the South American Subbasin.



Source: CSCGMP, 2006

Generalized Geologic Cross-Section of the South American Groundwater Subbasin Exhibit 3B.17-2

The underlying deeper aquifer zone is encountered within the Mehrten formation at depths below 300 feet and is separated from the shallow layer by a semi-confining layer that runs east to west. The base of the deep aquifer is approximately 1,400 feet below the ground surface. Large municipal wells constructed by the Sacramento County Water Agency (SCWA) have targeted the deeper layer because the deep layer generates higher production rates and impacts domestic wells to a smaller degree (Tully & Young, Inc., 2008).

Intensive use of groundwater over the past 60 years has resulted in a general lowering of groundwater elevations within the upper aquifer. Over time isolated groundwater depressions have grown and coalesced into a single cone of depression that is centered in the southwestern portion of the South American Subbasin, near the City of Elk Grove. This circumstance in turn has resulted in groundwater elevations within the central portion of the Subbasin that range from 40 feet above to 40 feet below mean sea level (msl) and, in the northern section of the Subbasin, 120 feet above to 30 feet below msl.

Based on available information from Olmstead and Davis (1961), DWR calculated groundwater storage capacity within the South American subbasin at 4,816,000 AF. Sources of recharge include natural and applied water recharge, which totals 257,168 AF. Subsurface inflow and outflow are not known specifically, but net subsurface outflow is estimated at 29,676 AFY. Other groundwater outflows include annual urban extraction of 68,058 AF and agricultural extraction of 162,954 AF (DWR, 2003). Based on these estimates, the WFA determined the estimated long term average annual sustainable yield of groundwater from the Central Basin to be 273,000 AFY.

Currently, groundwater extractions are estimated to be 250,000 AFY basinwide (Central Sacramento County Groundwater Management Plan [CSCGMP], 2006). However, these pumping rates are expected to decline significantly with the initiation of the operation of the Freeport Project in 2009, which will allow for SCWA to meet a large portion of its current groundwater demand with surface water. The demand for groundwater is not expected to reach these levels again until 2030.

Eastern County Replacement Water Supply Project

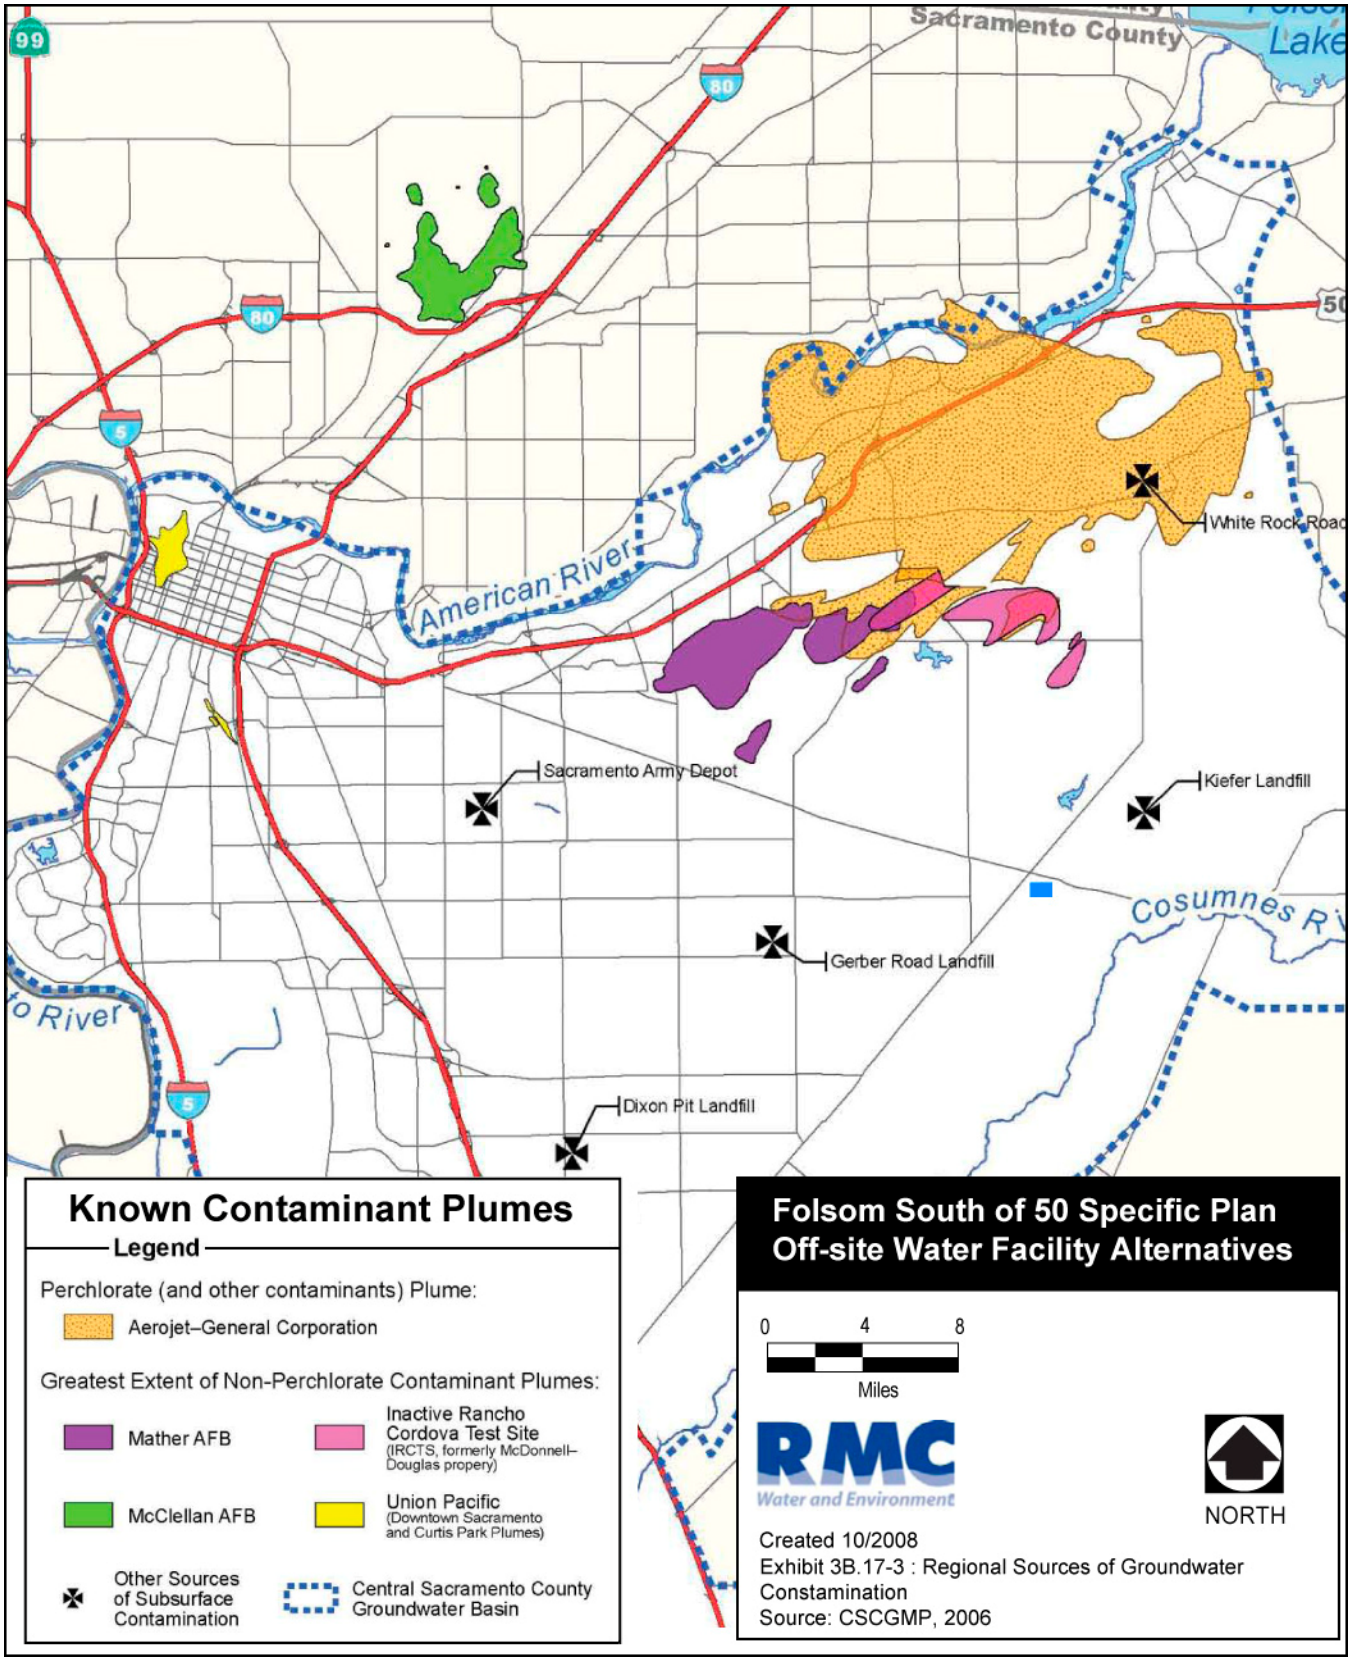
Under an agreement with Aerojet, SCWA is proposing the Eastern County Replacement Water Supply Project (RWSP) in eastern Sacramento County. The RWSP would consist of a system of conveyance facilities (i.e., pipelines and pump stations) to transport remediated water from groundwater extraction and treatment (GET) facilities to surface streams with discharge points along the American River. The GET-remediated water would be diverted at Reclamation's Folsom South Canal (FSC), the City of Sacramento's Fairbairn WTP diversion, and the Freeport Project. Diverted GET-remediated water would be delivered to the Golden State Water Company (GSWC) and the Cosumnes River via the FSC, Cal-American Water Company (Cal-Am) via the Fairbairn diversion, and SCWA wholesale and retail customers via the Freeport Project. No new diversion facilities are part proposed as part of the RWSP. Under the proposed RWSP, water for SCWA users would be diverted at the Freeport Project and treated at the Vineyard Surface WTP.

As discussed above, the GET facilities have already undergone CEQA environmental review and are under construction. The RWSP DEIR (State Clearinghouse No. 2004042122) was circulated for public review in October 2006. To the City's knowledge, SCWA does not anticipate implementing the RWSP in its entirety as described in the DEIR and will be seeking changes to its agreement with Aerojet.

Groundwater Quality

Water quality within the South American Subbasin is typically of good quality and suitable for potable use and meets water quality objectives. The concentration of TDS ranges from 24 to 581 milligrams per liter (mg/L) and averages 221 mg/L (DWR, 2003).

Exhibit 3B.17-3 illustrates regional sources of significant groundwater contamination within the North American Subbasin. Included are three EPA Superfund sites: Aerojet, Mather Field, and the Sacramento Army Depot. The other sites include the Kiefer Boulevard Landfill, an abandoned PG&E site on Jiboom Street near Old



Regional Sources of Groundwater Contamination **Exhibit 3B.17-3**

Sacramento, and the Southern Pacific and Union Pacific Rail Yards in downtown Sacramento. Although other localized plumes exist in and around the South American Subbasin (e.g., small leaking underground fuel tanks), the principal plumes shown in Exhibit 3B.17-3 are the largest and have the greatest current impact on existing groundwater use. For the Mather Field plumes, the primary constituents of concern (COC) are tetrachloroethylene (TCE), perchloroethylene (PCE), and carbon tetrachloride. For the Aerojet and Inactive Rancho Cordova Test Site (IRCTS) plumes, the primary COCs are TCE, n-nitrosodimethylamine (NDMA), and perchlorate.

3B.17.2 REGULATORY FRAMEWORK

FEDERAL PLANS, POLICIES, REGULATIONS, AND LAWS

Safe Drinking Water Act

The Safe Drinking Water Act (SDWA) was established to protect the quality of drinking water in the United States. The SDWA focuses on waters actually or potentially designated for drinking use, whether from surface or underground sources. The SDWA authorized the EPA to establish safe standards of purity and requires all owners or operators of public water systems to comply with primary (health-related) standards. State governments, which may assume this power from EPA, also encourage attainment of secondary standards (nuisance-related standards). COCs in a domestic water supply are those that either pose a health threat or in some way alter the aesthetic acceptability of the water. These types of contaminants are currently regulated by EPA as primary and secondary maximum contaminant levels (MCLs). Primary and secondary MCLs are established for COCs including turbidity, TDS, chloride, fluoride, nitrate, priority pollutant metals and organic compounds, selenium, bromate, trihalomethane precursors, radioactive compounds, and gross radioactivity. The SDWA includes the Wellhead Protection Program and the Underground Injection Control (UIC) program wells to prevent degradation of groundwater supplies. Water supplies delivered by the Off-site Water Facilities would be required to comply with the drinking water standards set by EPA.

STATE PLANS, POLICIES, REGULATIONS, AND LAWS

Groundwater Management Act (AB 3030)

California's Groundwater Management Act (California Water Code Sections 10750–10755.4 [AB 3030]) provides guidelines under which local agencies may adopt groundwater management plans. It promotes the voluntary development of groundwater management plans and provides criteria to ensure sustainable groundwater supplies for the future.

The Groundwater Management Act specifies the technical components of a groundwater management plan as well as the procedures for such a plan's adoption, including passage of a formal resolution of intent to adopt a groundwater management plan and holding a public hearing on the proposed plan. The Act also allows agencies to adopt rules and regulations to implement an adopted plan, and empowers agencies to raise funds to pay for the facilities needed to manage the basin, such as extraction wells, conveyance infrastructure, recharge facilities and testing and treatment facilities. The passage of SB 1938 in 2002 also required basin management objectives and other additions to be included in the groundwater management plans to comply with California Water Code Section 10750 et seq.

State Drinking Water Program

The California Department of Public Health (CDPH) Drinking Water Program is responsible for implementation of the Federal SDWA, as well as California statutes and regulations related to drinking water. The Division of Drinking Water and Environmental Management develops and implements the Drinking Water Source Assessment Program (DWSAP). The DWSAP Program describes CDPH's procedures for conducting drinking water source assessments, such as location of the drinking water source, and delineation of zones (based on

readily available hydrogeologic information on ground water flow, recharge, and discharge, and other information deemed appropriate by the state).

The CDPH regulates the operation of potable and recycled water systems, issues operating permits for these facilities, reviews plans and specifications for new facilities, enforces laws and regulations including the SDWA, and reviews water quality monitoring results. Furthermore, CDPH also conducts source water assessments and evaluates projects using injection and extraction into potable groundwater basins.

Central Valley Regional Water Quality Control Plan

The Central Valley RWQCB (Region 5) is responsible for the protection of beneficial uses of surface water and groundwater resources within the Sacramento River Basin. The Central Valley RWQCB uses planning, permitting, and enforcement authorities to meet this responsibility and has adopted a Water Quality Control Plan (Basin Plan) for the Sacramento River and San Joaquin River Basins and water quality objectives for groundwater (Central Valley RWQCB, 2004).

Although not a part of the regional water quality control plan, the SWRCB also has an adopted State Anti-Degradation Policy (SWRCB Resolution No. 68-16). This policy specifies that any new supply of water recharged into the basin must not degrade the existing groundwater basin unless change is consistent with maximum benefit to people of state and will not unreasonably affect present and potential beneficial uses.

REGIONAL AND LOCAL PLANS, POLICIES, REGULATIONS, AND LAWS

Sacramento County General Plan

The Sacramento County General Plan Conservation Element includes the following goals and policies that are relevant to the Off-site Water Facilities:

GOAL: Adequate long-term quantity and high quality of ground water resources for both human and natural systems.

- **Policy CO-22:** Development entitlements shall not be granted in areas where no ground water exists and water purveyors have reached their capacity to deliver treated water unless all necessary agreements and financing to obtain additional water supply are secured.

- **Policy CO-27:** Maintain agricultural zoning, and existing agricultural uses, in primary aquifer recharge areas identified as having a moderate to very high recharge capability Rezone applications for categories other than agricultural within one quarter mile of ground water recharge capability boundaries shall supply hydrologic data pertinent to recharge capability before the rezone application shall be considered complete.

- **Policy CO-29:** Discourage any nonagricultural land use in unincorporated areas with moderate to very high ground water recharge capability which could allow the percolation of pollutants into the ground water table.

Sacramento County Groundwater Ordinance

Title 3, Section 3.40.090 of the Sacramento County Water Code addresses the export of groundwater and surface water within the County. The ordinance requires that groundwater and surface water not be transported from the County without a permit issued by the Sacramento County Department of Water Resources. This ordinance does not apply to public water purveyors providing water service in two or more counties within a legally defined service area.

Sacramento Water Forum

The City and SCWA participated in the Water Forum process and are signatories to the WFA. The WFA supports the City's pursuit of additional water supplies and includes SCWA's need for increased surface water diversions. SCWA's "Purveyor Specific Agreement" also commits it to certain limitations on its use of water supplies, including groundwater. SCWA agreed to divert surface water at or near the mouth of the American River or from the Sacramento River. It agreed to limit its maximum surface water diversions to 78,000 AFA within the "South County M&I Users Group" area within Zone 40. An additional area within Zone 40 that overlaps the City of Sacramento's American River water rights settlement contract place of use is considered in the Water Forum Agreement and considers a long-term average demand of 9,300 AFA and up to 12,000 AFA in any single year.

As described in the Freeport Project EIR/EIS, SCWA anticipates diverting up to 90,000 AFA by 2030 (in any single year) to serve all areas within Zone 40 with surface water (FRWA, 2003). In addition to recognizing the need for surface water supplies, the WFA also sets a sustainable yield for the central county groundwater basin 273,000 AFA. Of this yield, SCWA expects to produce a long-term average of approximately 41,000 AFA from groundwater resources.

Sacramento Groundwater Authority Groundwater Management Plan

SGA is a joint powers authority responsible for the protection of the portion of the North American Subbasin within Sacramento County. SGA adopted a groundwater management plan in December 2003 with the goal of ensuring viable groundwater resources for agricultural, industrial, municipal, environmental, and aesthetic uses (SGA, 2003). Specifically, the plan's objectives are to maintain or improve groundwater quality and elevations, protect against land subsidence and impacts to surface water flows, and protect against impacts to water quality in the American River resulting from interaction between groundwater and surface water in the American River basin (SGA, 2003). As previously indicated, the NCMWC's service area overlies western portions of this subbasin.

Central Sacramento County Groundwater Management Plan

The CSCGMP is the result of the WFA and the Water Forum Successor Effort (Successor Effort), which ultimately formed the Central Sacramento County Groundwater Forum. The Central Sacramento County Groundwater Forum developed the CSCGMP to assist in delineating roles and responsibilities of participating agencies and individuals in the management of the groundwater basin. The CSCGMP outlines five Basin Management Objectives (BMOs) that are designed to protect and enhance the groundwater basin and includes monitoring and management programs to ensure the BMOs are being met.

Sacramento Valley Integrated Regional Water Management Plan

The Northern California Water Association (NCWA), as administrator of the Joint Exercise of Powers Agreement for Northern California, coordinated the preparation of the Sacramento Valley Draft Integrated Regional Water Management Plan (IRWMP), which includes Zones 1, 2, and 3 of the Off-site Water Facilities Study Area (NCWA, 2006). Objectives outlined in the Draft IRWMP that are related to the Off-site Water Facilities include a groundwater management and monitoring program with the purpose of improving regional and local water supply reliability. Under the Draft IRWMP, siting of groundwater wells should be conducted so as to be dispersed in location in order to spread project benefits and minimize environmental and third-party impacts. Other goals of the plan in relation to groundwater include promoting recharge facilities, ensuring recharge areas are not impacted by urban development, supporting distribution facilities, and allocation of facilities to allow for monitoring groundwater levels, quality, and recharge.

3B.17.3 Environmental Consequences and Mitigation Measures

Thresholds of Significance

The thresholds for determining the significance of impacts for this analysis are based on the environmental checklist in Appendix G of the State CEQA Guidelines. These thresholds also encompass the factors taken into account under NEPA to determine the significance of an action in terms of its context and the intensity of its impacts. An impact to groundwater resources would be considered significant if the Off-site Water Facilities would result in any of the following effects:

- violate any water quality standards or waste discharge requirements or otherwise substantially degrade groundwater water quality;
- substantially deplete groundwater supplies or interfere substantially with groundwater recharge such that there would be a net deficit in aquifer volume or a lowering of the local groundwater table level (e.g., the production rate of pre-existing nearby wells would decline to a level which would not support existing land uses or planned uses for which permits have been granted); or
- groundwater pumping associated with operations of the Off-site Water Facilities would alter the existing surface hydrology.

Analysis Methodology

The potential impacts of the Off-site Water Facilities to groundwater resources were evaluated in terms of potentially foreseeable changes in groundwater levels and groundwater quality. Results for groundwater levels with and without the Off-site Water Facilities were compared for groundwater basins underlying the Off-site Water Facilities Study Area to determine the potential for both regional and local impacts or benefits. In evaluating the potential changes to groundwater levels or storage resulting from implementation of one of the Off-site Water Facility Alternatives, the City used the sustainable yields and demand projections established for the Northern and Central Sacramento County Groundwater Basin Management Plans by the WFA (SGA, 2003; CSCGMP, 2006).

Impact Analysis

Impacts that would occur under each of the Off-site Water Facility Alternatives are identified as follows:

NCP (No USACE Permit Alternative)

PA (Proposed Off-site Water Facility Alternative)

1 (Off-site Water Facility Alternative 1 – Raw Water Conveyance – Gerber/Grant Line Road Alignment and White Rock WTP)

1A (Off-site Water Facility Alternative 1A Raw Water Conveyance – Gerber/Grant Line Road Alignment Variation and White Rock WTP)

2 (Off-site Water Facility Alternative 2 Treated Water Conveyance – Douglas Road Alignment and Vineyard SWTP)

2A (Off-site Water Facility Alternative 2A Treated Water Conveyance – Excelsior Road Alignment Variation and Vineyard SWTP)

2B (Off-site Water Facility Alternative 2B Treated Water Conveyance – North Douglas Tanks Variation and Vineyard SWTP)

3 (Off-site Water Facility Alternative 3 Raw Water Conveyance – Excelsior Road Alignment and White Rock WTP)

3A (Off-site Water Facility Alternative 3A Raw Water Conveyance – Excelsior Road Alignment Variation and White Rock WTP)

4 (Off-site Water Facility Alternative 4 Raw Water Conveyance – Easton Valley Parkway Alignment and Folsom Boulevard WTP)

4A (Off-site Water Facility Alternative 4A Raw Water Conveyance – Easton Valley Parkway Alignment Variation and Folsom Boulevard WTP).

The impacts for each alternative are compared relative to the PA at the end of each impact conclusion (i.e., similar, greater, lesser).

IMPACT 3B.17-1 Exceedance of Water Quality Standards and Requirements for Groundwater. *The Off-site Water Facility Alternatives could generate discharges to or contribute to the depletion of groundwater resources thereby potentially directly and indirectly violating water quality standards or waste discharge requirements.*

NCP, PA, 1, 1A, 2, 2A, 2B, 3, 3A, 4, and 4A

Construction-Related Impacts

Construction of the Off-Site Water Facilities pipelines, pump stations, and WTP would, at times, require dewatering of shallow, perched groundwater in the immediate vicinities of excavations and installation of underground features at a limited number of areas where groundwater depths are shallow. In order to create safe working conditions, free of standing water, when needed, shallow groundwater wells would be installed to lower groundwater elevations in the immediate vicinity of boring shafts to about 15 to 30 feet below the ground surface. During trenchless construction, dewatering would be necessary to remove water from tunnel, launching, and receiving pits. It is not known how much water would be withdrawn because the volume would be influenced by the local shallow aquifer character, the depth of excavation, and the duration that subsurface work is conducted.

Groundwater withdrawn from the construction areas would be subsequently discharged to local waterways or drainage ditches, or via land application. These discharges may contain sediments, dissolved solids, salts, and other water quality constituents found in the shallow groundwater, which could degrade the quality of receiving waters. Degradation of local receiving waters from the introduction of shallow groundwater during construction dewatering could result in a **potentially significant direct** and **indirect** impact to receiving waters. ***[Similar]***

Operational Impacts

The proposed assignment of 8,000AFY of surface water from NCMWC to the City would not require NCMWC to the supplement its supplies to meet irrigation demands by pumping groundwater in its service area. NCMWC has sufficient water supplies to meet its 2007 irrigation demands with or without the proposed transfer. As result, the proposed assignment would not have any adverse impacts to groundwater resources underlying NCMWC's Service Area within the North American Subbasin.

Likewise, with no increase in groundwater pumping within the NCMWC service area, there is no potential to influence the distribution and extent of existing contamination of the shallow aquifer at McClellan Air Force Base. This contamination resulted from military and related operations on the Air Force Base, and is comprised of a wide array of toxic chemicals including volatile organic carbons, solvents, PCBs, heavy metals, and jet fuel. A remediation plan is presently underway and this contamination site is located over 3 miles away from NCMWC. However, the groundwater plume is not fully contained or remediated (EPA, 2005) and may be susceptible to movement by operations of nearby wells. Given that no increased well use is proposed in conjunction with the

Off-site Water Facilities, it is reasonable to conclude that the Off-site Water Facilities would not directly or indirectly affect or alter the distribution of this contaminant zone. Based on these considerations, these **direct** and **indirect** impacts would be **less than significant**. ***[Similar]***

Mitigation Measure 3B.17-1a: Implement Construction Dewatering Best Management Practices.

During construction at site locations containing high groundwater, if groundwater from dewatering activities cannot be contained within the construction area (e.g., pipeline corridor, WTP), it shall be pumped to an authorized onsite land area, existing detention facilities, or Baker tanks or equivalent with sufficient capacity to control the volume of groundwater. Tanks shall be equipped with either a gel coagulant, a filter system, or other containment to remove sediment. The Off-site Water Facilities Stormwater Pollution Prevention Plan (SWPPP) shall include BMPs, as appropriate, to retain, treat, and dispose of groundwater from dewatering activities. Measures shall include, but not limited to, the following:

- temporarily retain pumped groundwater, as appropriate, to reduce turbidity and concentrations of suspended sediments before discharge to surface waterways;
- convey pumped groundwater to a suitable land disposal area capable of percolating flows; and/or
- incorporate other applicable measures from the Caltrans Storm Water Quality Handbook, Section 7: Dewatering Operations (2004).

Implementation: City of Folsom Utilities Department

Timing: Prior to and during construction

Enforcement:
1. California Department of Fish and Game or Regional Water Quality Control Board
2. City of Folsom Community Development Department.
3. Sacramento County Planning Department or City of Rancho Cordova Planning Department for improvements within their respective jurisdictions.

Mitigation Measure 3B.17-1b: Implement a Dewatering Discharge Monitoring Program.

A groundwater discharge monitoring program shall be implemented to ensure that receiving water quality does not exceed levels that would impact aquatic resources and agricultural use. If monitoring reveals that water quality would impact these beneficial uses, discharges to surface waterways shall be reduced or diluted to acceptable levels, or terminated. If discharges are reduced or terminated, groundwater shall be disposed through land application. Groundwater collected during dewatering shall be tested for contamination prior to disposal and comply with Central Valley RWQCB requirements.

Implementation: City of Folsom Utilities Department

Timing: Prior to and during construction

Enforcement:
1. California Department of Fish and Game or Regional Water Quality Control Board
2. City of Folsom Community Development Department.

3. Sacramento County Planning Department or City of Rancho Cordova Planning Department for improvements within their respective jurisdictions.

With the implementation of the above mitigation measures, impacts to groundwater quality under the Off-site Water Facility Alternatives would be reduced to a **less-than-significant** level by ensuring that all dewatering discharges are properly managed in accordance with RWQCB requirements and, if determined necessary, receive appropriate treatment prior to off-site discharge.

IMPACT 3B.17-2 Depletion of Groundwater Supplies Through Pumping. *The Off-site Water Facility Alternatives is unlikely to substantially deplete groundwater supplies or interfere substantially with groundwater recharge such that there would be a net deficit in aquifer volume or a lowering of the local groundwater levels.*

NCP, PA, 1, 1A, 3, 3A, 4, and 4A

Construction Impacts

The Off-Site Water Facility Alternatives would include the construction of impermeable surfaces associated with the WTP and storage tanks. Construction of these impermeable surfaces would affect groundwater recharge onsite. However, these impermeable surfaces would be limited in extent to less than one half of the 10-acre WTP (including buildings, paved roads, storage and treatment facilities, and parking lots) and only a portion of the well sites (including access roads and auxiliary facilities). This area would be very small in comparison to adjacent areas that would remain open and permeable. Therefore, **direct** impacts to groundwater recharge associated with these impermeable surfaces would be **less than significant**. ***[Similar]***

Groundwater dewatering may be necessary during construction of portions of the untreated and treated water pipelines, and the WTP. Dewatering activities would temporarily reduce groundwater levels to approximately 15 feet below ground surface within and directly adjacent to construction areas. During trenchless construction, dewatering may be necessary to remove water from tunnel, launching, and receiving pits. These impacts would be temporary in duration and highly localized to areas within and directly adjacent to construction activities. Although the limited dewatering activities under construction of the Off-site Water Facility Alternatives would cause a highly localized lowering of the groundwater table, they would not cause a net deficit in aquifer volume or a lowering of the groundwater table in the South American Basin. Therefore, these in**direct** impacts would be **less than significant**. ***[Similar]***

Operational Impacts

The operation of the Off-site Water Facility Alternatives could involve impacts to the South American Subbasin. Specifically, implementation of the Off-site Water Facility Alternatives involves the City's acquisition of a portion of SCWA's 85 mgd capacity within the Freeport Project, which could result in a reduction in SCWA's ability to meet peak demands, at times, with surface water alone. As a result, this analysis assumes that SCWA may be required to pump additional groundwater in place of the capacity transferred to the City to meet SCWA's peak demands to the extent it becomes necessary as demand increases in future years. For the purposes of this analysis, the resulting impact on groundwater would be equal to the purchased conveyance capacity of 6.5 mgd or 7,280 AFY. This action could require that SCWA pump more than 41,000 AFY of groundwater in future years.

As previously indicated in the setting discussion, the WFA sets the sustainable yield for the South American Subbasin at 273,000 AFY. Based on information contained in the Freeport Project EIR (2003) and CSCGMP (2006), current groundwater demands (2005) within the South American Subbasin are estimated at 250,000 AFY. Of this total, SCWA currently pumps, on average, 131,000 AFY. With the completion of the Freeport Project,

SCWA anticipates diverting up to 90,000 AFY[2] of surface water during normal years thereby reducing its groundwater pumping to 41,000 AFY. This initial reduction in groundwater demand from SCWA would reduce total groundwater demand within the South American Subbasin to 159,000 AFY. Given that the Freeport Project would be online in advance of the operation of the Off-site Water Facility Alternatives, even if SCWA is required to pump groundwater in place of the conveyance capacity lost by the Off-site Water Facilities, this pumping would occur at SCWA's existing well facilities with total groundwater demands under a worst-case, critical-dry-year scenario increasing to 166,280 AFY. As a result, **direct** and **indirect** impacts to groundwater resources under existing conditions would be **less-than-significant**. ***[Similar]***

Over the longer-term, total water demands within the South American Subbasin are estimated to approach approximately 255,000 AFY[3][4] in the year 2030 for a critically dry year (CSCGMP, 2006). Total groundwater demand becomes substantially reduced at 235,000 AFY during wet and normal years when surface water supplies are available, thereby allowing the basin to recharge. With the Off-site Water Facilities and assuming that groundwater is used to augment SCWA's peak water demands in response to SCWA's reduced conveyance capacity within the Freeport Project, the corresponding increase in total groundwater demands could approach 262,280 AFY[5] by 2030. This estimate is short of the 273,000 AFY sustainable yield estimate for the South American Subbasin based on the WFA and leaves a margin of 10,720 AFY of available capacity for other potential users under future conditions. Because groundwater pumping directly and indirectly associated with the Off-site Water Facilities would not exceed the sustainable yield recommendations, groundwater levels within the South American Subbasin under future conditions are projected to remain at levels above than those accepted by the WFA. Based on these findings, this **direct** and **indirect** impact is considered **less-than-significant**. ***[Similar]***

Impacts to the North American Groundwater Basin

Implementation of the Off-site Water Facilities would not require the NCMWC to replace the assigned surface water supplies with groundwater. As previously indicated in Chapter 2, "Alternatives," a study prepared by Wagner and Bonsignore (2007) concludes that the proposed assignment of CVP water from NCMWC to the City would have no indirect adverse effect on cropping patterns in terms of water availability during normal and wet years. Even during drier years, groundwater pumping should not be required by NCMWC to augment the surface water supplies transferred to the City assuming a continuation of 2007 cropping and irrigation patterns. Based on these circumstances, the **direct** and **indirect** impacts would **less-than-significant**. ***[Similar]***

Mitigation Measure: No mitigation measures are required.

2, 2A, and 2B

Off-site Water Facility Alternatives 2 and 2A would involve the construction of treated-water conveyance lines from SCWA's existing Vineyard SWTP or the planned Douglas Storage Tanks. However, under these alternatives no new WTP would be constructed and new facilities proposed under these alternatives would generally be contained within existing roadways and/or developed areas. For this reason, these alternatives would have negligible or **no impact** on groundwater recharge. ***[Lesser]***

These alternatives would involve the purchasing of capacity within the Freeport Project and, therefore, those potential impacts to groundwater levels identified for the Preferred Off-site Water Facility Alternatives would apply to Off-site Water Facility Alternatives 2, 2A, and 2B.

---

[2] SCWA's total surface water supplies for Zone 40 are assumed to include 68,500 AFA in CVP and appropriated supplies and 12,000 AFA and 9,300 AFA from the Purveyor Specific Agreement with the City of Sacramento.

[3] A conservation factor of 25.6% is applied to 2030 water demand estimates per the WFA.

[4] Groundwater use for 2030 assumes the inclusion of Aerojet GET extraction rates, estimated at 35,890 AFY.

[5] Estimate to account for City purchasing capacity within the Freeport Project is based on an average annual increase in pumping within SCWA's service are of 6.5 mgd or 7,280 AFY.

Mitigation Measure: No mitigation measures are required.

IMPACT 3B.17-3 Alteration of Surface Water Hydrology through Substantial Groundwater Pumping. *Substantial groundwater pumping from the Excelsior Well Field required by Off-site Water Facilities operations could alter existing surface hydrology.*

NCP, PA, 1, 1A, 2, 2A, 2B, 3, 3A, 4, and 4A

As part of the proposed Off-site Water Facility Alternatives, the City would acquire conveyance capacity within the Freeport Project. As previously discussed, the capacity allocated to the City would reduce SCWA's total dedicated capacity within the Freeport Project. This could require that SCWA rely more on groundwater extracted from existing well sites, such as the Excelsior Well Field, to meet long-term water demands.

The interaction between groundwater and surface water has not been extensively evaluated in the South American Basin. A recent draft decision by the SWRCB (2003) regarding the American River concluded that from Nimbus Dam to about 6,000 feet below the dam, groundwater elevations and surface water elevations were similar enough to each other that groundwater could be tributary to the American River. Beyond 6,000 feet down river from the dam, groundwater elevations are sufficiently lower than the river channel to conclude that the American River is a "losing" stream down to its confluence with the Sacramento River.

No new wells would be constructed as part of the Off-site Water Facility Alternatives. Any additional pumping by SCWA would likely occur at the existing Excelsior Well Field, which generally operates at depths that would be expected to provide sufficient separation between the existing wells and the American River, which is more closely linked to groundwater associated with the Laguna formation. Given that these wells tap geologic materials substantially lower than the Laguna formation and are located over six miles south of the River, any increased operation of the well field is not expected to result in significant adverse effects to surface water flows within the American River and would remain within the safe yield for the basin. Further, once the Freeport Project is in operation and surface water supplies becomes available, SCWA's use of the Excelsior Well Field for groundwater pumping is expected to diminish significantly. Therefore, this **direct** impact is considered **less-than-significant**. **No indirect** impacts would occur. ***[Similar]***

Further, the Freeport Project EIR/EIS provided a programmatic evaluation of groundwater banking within the Central Sacramento Groundwater Basins. At the time, the FRWA concluded that the banking within the Central Basin was not feasible due to the lack of a Groundwater Management Plan (AB 3232). However, since the Freeport Project EIR/EIS's preparation, the CSCGMP has been adopted as part of the WFA Successors Effort and, thereby, removing a significant institutional obstacle that existed in 2003. Based on these considerations, the operation of the Off-Water Facility alternatives would result in **no impacts** to surface water flows as a result of increased groundwater pumping. ***[Similar]***

Mitigation Measure: No mitigation measures are required.

3B.17.4 RESIDUAL SIGNIFICANT IMPACTS

Operation of the Off-site Water Facility Alternatives would not result in residual, project-specific significant and unavoidable impacts to the quality and quantity of local and regional groundwater resources. With the implementation of the prescribed dewatering mitigation, construction-related impacts to shallow groundwater would be minimized to a less-than-significant level through the proper control, treatment, and containment of pumped groundwater prior to off-site discharge.

This section was prepared by RMC Water and Environment.

3A.18 WATER SUPPLY - LAND

3A.18.1 AFFECTED ENVIRONMENT

Presently, there are no public water supply facilities on the "Land" portion of the project site. Approximately 3,330 acres of the "Land" portion of the project site would be within the City of Folsom's service area and the remaining 172 acres generally east of Empire Ranch Road would be within the El Dorado Irrigation District (EID) service area. It is assumed that the City would provide treated water to EID for its service area within the project site; however, water supplies delivered in EID's service area would be controlled by EID (Tully & Young 2010: 8). The City has proposed a separate, but related "Water" Project in conjunction with the project, to meet projected water demands at build-out, which is described in Chapter 2, Alternatives. The "B or Water" portions Chapter 3 provide an analysis of "Water" project alternatives or Off-site Water Facility Alternatives proposed by the City in conjunction with the approval of the project.

WATER SUPPLIES

Water demands for the project would be met by securing an assignment of an 8,000 acre-foot per year Sacramento River surface water supply from the Natomas Central Mutual Water Company (NCMWC) pursuant to NCMWC's contract with the United States Bureau of Reclamation (Bureau of Reclamation). That supply would be subject to a 25% reduction in certain contractually-defined dry years. The water supply identified for the project is an entirely new source for the service areas of both the City and EID and would therefore not affect any existing water supply operations in those service areas (Tully & Young 2010: 7).

NCMWC is a private Mutual Water Company as defined in the California Public Utilities Code, Section 2705, formed for the delivery of water at cost to its shareholders. NCMWC is subject to local land use controls, including those of Sacramento and Sutter Counties and the City of Sacramento. The service area of NCMWC is defined by its contract with the Bureau of Reclamation for diversion of water from Sacramento River sources and for water service from the Central Valley Project (CVP). The NCMWC service area encompasses approximately 53,537 acres in the interior portion of the Natomas Basin in northern Sacramento County and southern Sutter County. NCMWC diverts water from the Sacramento River and the Natomas Cross Canal (NCC). This water is used to provide irrigation water for agricultural use and habitat preservation, and untreated water is also used for golf course and landscape irrigation.

NCMWC currently distributes water through five primary irrigation systems: the Northern System, the Bennett System, the Central System, the Elkhorn System, and the Riverside System. These irrigation systems are linked and used to support each other, and each system is served by a pumping facility located either along the Sacramento River or the NCC. The five pumping plants maintain a total maximum water diversion capacity of 630 cubic feet per second (cfs), or approximately 1247.4 acre-feet per day. Drainage and flood control for the Natomas Basin is provided by Reclamation District 1000 (RD 1000), which has a coinciding service area with NCMWC and shares several joint use facilities.

NCMWC"s existing water license/permit; place of use; purpose of use; and diversion periods, amounts, and limits are shown in Table 3A.18-1. NCMWC's total estimated long-term average annual supply of surface water is 120,200 acre-feet per year (AFY). A distribution of NCMWC's monthly diversion entitlements is provided in Table 3A.18-2. The maximum reduction in NCMWC's diversions during any critically dry year is 25%.

Chapter 2, "Alternatives," provides additional description of NCMWC's service area, its associated CVP water rights, and how a portion of those supplies would be permanently assigned to the City. Section 3B.9, "Hydrology and Water Quality – Water," provided a detailed description of the hydrology of the Sacramento River along with additional description of NCMWC's service area.

Table 3A.18-1 NCMWC Surface-Water Entitlements					
License/Permit	Place of Use	Purpose of Use	Diversion Period	Diversion Amount (cfs)	Diversion Limit (afy)
1050	Reclamation Settlement Contract Service Area	Agricultural Irrigation and M&I	April 1 – October 1	42	Limited to 120,200 by the Reclamation Settlement Contract
2814			April 15 – October 15	38	
3109			May 1 – October 31	160	
3110			May 1 – October 1	120	
9794			April 1 – June 30	131

Water Diversion and Distribution Facilities

Under the City's "Water" Project, surface water would be diverted from the Sacramento River at the Freeport Regional Water Authority's (FRWA) diversion facility (Freeport Project) and conveyed through segments 1 and 2 of the Freeport Project and new conveyance pipeline constructed by the City to the project site. Water treatment would also be provided through the either the construction of an on- or off-site WTP or at the Vineyard Surface Water Treatment Plant (SWTP). (See Chapter 2, "Alternatives," for a detailed discussion of Off-site Water Facility Alternatives.)

Freeport Regional Water Project

The FRWA was created by exercise of a joint-powers agreement between SCWA and the East Bay Municipal Utility District (EBMUD). FRWA's basic purpose is to increase the reliability of water service for customers,

reduce rationing during droughts, and facilitate conjunctive use of surface-water and groundwater supplies in central Sacramento County. The FRWA developed the Freeport Regional Water Project (FRWP) to meet the objectives of SCWA and EBMUD.

A DEIR/DEIS was prepared and circulated for public review in July 2003 (SCH #2002032132), and the FEIR was certified in April 2004. No legal challenge was filed under CEQA or NEPA. FRWA subsequently completed federal Endangered Species Act (ESA) compliance in fall 2004, leading to Bureau of Reclamation's issuance of the record of decision in January 2005. Minor adjustments to the project were made after certification of the FEIR, and a supplemental initial study/mitigated negative declaration (IS/MND) was prepared and circulated for public review in February 2006. The supplemental IS/MND was adopted in March 2006.

The FRWP is currently nearing the completion of construction and estimated to be operational in summer 2010. Once operational, the FRWP will provide SCWA with up to 85 mgd of surface water from the Sacramento River that would be conveyed by FRWA to SCWA's Vineyard SWTP. The Vineyard SWTP is currently under construction and is anticipated to be completed by November 2011 (SCWA 2009).The remaining 100 mgd of the 185 mgd diverted from the Sacramento River would be conveyed past the Vineyard Surface WTP by EBMUD to the Folsom South Canal, which would convey the water to the Mokelumne Aqueduct for use within EBMUD's service area during dry years.

Pursuant to SWRCB Permit No. 21209, SCWA's total diversions at Freeport are permitted for up to 286 cfs, but not to exceed 71,000 AFY. On average, however, SCWA's diversions are initially estimated to be 21,700 AFY in 2010.

3A.18.2 REGULATORY FRAMEWORK

FEDERAL PLANS, POLICIES, REGULATIONS, AND LAWS

The following Federal plans, policies, regulations, and laws related to water supply are relevant to the off-site "Water" components of the Project, and are described in detail in Sections 3B.3 "Biological Resources – Water" and 3B.9, "Hydrology and Water Quality – Water:"

- Central Valley Project Improvement Act
- Safe Drinking Water Act
- Operations Criteria and Plan for Long-Term Operation of CVP/SWP

STATE PLANS, POLICIES, REGULATIONS, AND LAWS

The following state plans, policies, regulations, and laws related to water supply are relevant to the off-site "Water" components of the Project, and are described in detail in Section 3B.9, "Hydrology and Water Quality – Water:"

- Porter-Cologne Water Quality Control Act

Senate Bills 610 and 221

The State of California has enacted legislation that is applicable to the consideration of larger projects under CEQA. Senate Bill (SB) 610 (Chapter 643, Statutes of 2001; Section 21151.9 of the Public Resources Code and Section 10910 et seq. of the Water Code) requires the preparation of "water supply assessments" (WSAs) for large developments (i.e., more than 500 dwelling units or nonresidential equivalent), such as the Folsom South of Highway 50 Specific Plan. These assessments, prepared by "public water systems" responsible for serving project

areas (in this case, the City of Folsom and EID), address whether existing and projected water supplies are adequate to serve the project while also meeting existing urban and agricultural demands and the needs of other anticipated development in the service area in which the project is located. If the most recently adopted Urban Water Management Plan (UWMP) accounted for the projected water demand associated with the project, the public water system may incorporate the requested information from the UWMP. If the UWMP did not account for the project's water demand, or if the public water system has no UWMP, the project's WSA must discuss whether the system's total projected water supplies (available during normal, single-dry, and multiple-dry water years during a 20-year projection) would meet the project's water demand in addition to the system's existing and planned future uses, including agricultural and manufacturing uses.

A WSA has been prepared for the proposed project (Tully & Young 2010, on behalf of the City) and is included as Appendix M-I to this EIR/EIS. The conclusions of the WSA are summarized below in Section 3A.18.3, "Environmental Consequences and Mitigation Measures."

Where a WSA concludes that insufficient supplies are available, the public water system must provide to the city or county considering the development project its plans for acquiring and developing additional water supplies. Based on all the information in the record relating to the project, including all applicable WSAs and all other information provided by the relevant public water systems, the city or county must determine whether sufficient water supplies are available to meet the demands of the project, in addition to existing and planned future uses. Where a WSA concludes that insufficient supplies are available, the WSA must lay out the steps that would be required to obtain the necessary supply. The WSA is required to include (but is not limited to) identification of the existing and future water supplies over a 20-year projection period. This information must be provided for average normal, single-dry, and multiple-dry years. The absence of an adequate current water supply does not preclude project approval, but it does require a lead agency to address a water supply shortfall in its project findings.

If the proposed project is approved, additional complementary statutory requirements, created by 2001 legislation and known as SB 221 (Government Code Section 66473.7), would apply to the approval of tentative subdivision maps for more than 500 residential dwelling units. This statute requires cities and counties to include, as a condition of approval of such tentative maps, the preparation of a "water supply verification." The verification, which must be completed by no later than the time of approval of final maps, is intended to demonstrate that there is a sufficient water supply for the newly created residential lots. Government Code Section 66473.7 defines sufficient water supply as follows:

> …the total water supplies available during normal, single-dry, and multiple-dry years within a 20-year projection period that would meet the projected demand associated with the proposed subdivision, in addition to existing and planned future uses, including, but not limited to, agricultural and industrial uses.

A number of factors must be considered in determining the sufficiency of projected supplies:

- the availability of water supplies over a historical record of at least 20 years;
- the applicability of an urban-water-shortage contingency analysis that includes action to be undertaken by the public water system in response to water supply shortages;
- the reduction in water supply allocated to a specific water-use sector under a resolution or ordinance adopted or a contract entered into by the public water system, as long as that resolution, ordinance, or contract does not conflict with statutory provisions giving priority to water needed for domestic use, sanitation, and fire protection; and

- the amount of water that the water supplier can reasonably rely on receiving from other water supply projects, such as conjunctive use, reclaimed water, water conservation, and water transfer, including programs identified under federal, state, and local water initiatives.

REGIONAL AND LOCAL PLANS, POLICIES, REGULATIONS, AND LAWS

The following regional and local plans, policies, regulations, and laws related to water quality and flooding are relevant to the Off-site Water Facilities alternatives, and are described in detail in Section 3B.9, "Hydrology and Water Quality – Water" and 3A.10, "Land Use and Agricultural Resources – Land:"

- Sacramento Water Forum
- Measure W

Sacramento County General Plan

There are no goals and policies of the Sacramento County General Plan (1993) related to water supply that are applicable to the Proposed Project or alternatives under consideration.

El Dorado County General Plan

There are no goals and policies of the El Dorado County General Plan (2004) related to water supply that are applicable to the Proposed Project or alternatives under consideration.

City of Folsom General Plan

The following goals and policies of the City of Folsom General Plan (1988) are applicable to the Proposed Project and the other four action alternatives. There are no City of Folsom goals and policies that would apply to the No Project Alternative.

GOAL 40: To set targets for ultimate build-out of the City, to plan for the provision of public facilities and services to meet this level of development, and to phase development according to the capacity of public facilities and services to meet those targets.

- **Policy 40.1:** No permit for construction shall be issued for any new development not served by existing municipal facilities until the following conditions have been met:

    - The applicant can provide for the installation and/or financing (through fees or other means) of needed public facilities.

    - The project is included in the area covered by an existing facilities plan approved by the City.

    - The project can be served by on-site or private facilities meeting City and County health and safety requirements.

- **Policy 40.2:** The City shall require the preparation of a facilities plan for an identified area when:

    - Development of an area necessitates the provision, extension, and/or expansion of municipal services and facilities which are not customarily constructed by a developer, or

    - There is a need for services or facilities not otherwise funded by regular City fees, or

    - The construction of the necessary services and facilities cannot be logically or economically provided by one landowner/development in the normal sequence of orderly development.

- **Policy 40.3:** An area facilities plan shall include, but not limited to the following:

  - Description of the plan area, the basis for the selection of the proposed boundaries, and the development potential of the area which is based on a comprehensive land use map.

  - A statement of the plan's consistency with the Folsom General plan and the City's Urban Development Policy.

  - Identification of the nature and extent of facilities necessary to serve the area and a schedule of estimated time within which facilities must be constructed.

  - Engineer's estimate of the total cost of such improvements (including plan preparation).

  - A plan for the equitable apportionment of costs among benefited properties and adjustments thereof based on the time such costs are paid.

  - The nature of the obligation of each land-owner or developer.

  - Discussion of the options available to finance the improvements including, but not limited to, construction by developers.

  - Provisions for amendments to the plan which may result from changes in the plan area, development patterns, etc.

  - Provisions to refund or reimburse landowners who construct facilities with capacity beyond the ultimate need of their developments.

  - A statement which recognizes that the financial commitments required pursuant to such plans are not in lieu of other municipal service and facilities fees. The financial commitments of landowners/developers shall be taken into account by the City in determining the extent of the imposition of such other municipal service and facilities fees.

  - A statement which recognizes that the area facilities plan is not intended to be responsible for the provision of all possible public facilities that will be needed in the future and that there are or may be additional costs/fees established by the City and other jurisdictions (such a school district) that may apply to the area. However, the plan must address the need for public facilities which may reasonably be assumed to be necessary during buildout of the area.

  - Provisions for administration of the area plan and the collection and distribution of funds.

- **Policy 40.5:** The City shall annually monitor the City's available municipal water supply to ensure adequate reserves exist to serve projected water demand. In the event projected demand exceeds supply, the City may take the following actions to prevent the anticipated shortfall.

  - Condition development approvals on the availability of identified water supplies.

  - Building permits covered by the former General Plan area should be restricted until such time as the City determines adequate supplies exist to allow unrestricted hookups to the municipal water system.

  - Within the area known as the East Area Facilities Plan Area consisting of approximately 3,900 acres, and any area south of U.S. Highway 50 which could be annexed to the City, the City shall not approve a final subdivision map or final parcel map, or other entitlement which would permit the commencement of construction until such time as the City has acquired an additional water supply which is adequate to

supply such development as required under the Urban Development Policy. This prohibition shall not preclude the approval of final parcel maps covering all or a portion of the property covered by an approved tentative subdivision map, where multiple final subdivision maps are to be filed pursuant to Government Code Section 66456.1.

3A.18.3 Environmental Consequences and Mitigation Measures

Thresholds of Significance

The thresholds for determining the significance of impacts for this analysis are based on the environmental checklist in Appendix G of the State CEQA Guidelines. These thresholds also encompass the factors taken into account under NEPA to determine the significance of an action in terms of its context and the intensity of its impacts. The Proposed Project or alternatives under consideration were determined to result in a significant impact related to water supply if they would do any of the following:

- require or result in the construction of new water treatment facilities or expansion of existing facilities, the construction of which could cause significant environmental effects; or
- have insufficient water supplies available to serve the project from existing or permitted entitlements and resources, or require new or expanded entitlements.

Analysis Methodology

Impacts on potable water supplies and conveyance facilities that would result from implementation of the Proposed Project and alternatives under consideration were identified by comparing existing service capacity and facilities with future demand associated with project implementation. Potential demands for water and impacts on infrastructure were evaluated based on a review of the *City of Folsom General Plan* (City of Folsom 1988) and the *Folsom Specific Plan SB 610 Water Supply Assessment* (Tully and Young 2010).

A quantitative comparison was used to determine impacts of the project on water supply future demands. Table 3A.18-3 summarizes water supply demands for the Proposed Project and the four action alternatives under consideration.

Table 3A.18-3
Folsom South of U.S. 50 Specific Plan Water Demands

Land Use Development Alternative	Normal-Year Water Demands (AFY)			Single-Dry and Multiple-Dry Year Water Demands (AFY)		
	City of Folsom	EID	Total	City of Folsom	EID	Total
Proposed Project	5,166	255	5,422	5,315	262	5,577
Resource Impact Minimization	4,238	210	4,449	4,363	217	4,580
Centralized Development	4,566	41	4,606	4,694	42	4,737
Reduced Hillside Development	5,168	228	5,395	5,312	235	5,547
No USACE Permit	3,967	231	4,198	4,091	239	4,330

Notes: Notes: AFY = acre-feet per year; EID = El Dorado Irrigation District
Development of residences under the No Project Alternative would not be served by a municipal water service provider.
Source: Tully and Young, 2010 and AECOM, 2010

As described in Chapter 2, "Alternatives" the "Water" portion of the project takes the form of a series of Off-site Water Facility Alternatives in conjunction with development of the SPA to supply the projected water demands through build-out. These Off-site Water Facility alternatives each would involve the construction of new water conveyance and treatment facilities. The environmental effects of the Off-site Water Facility Alternatives are evaluated at an equal level of detail throughout the Chapter 3 in the "Water – B" analysis and are summarized in the Executive Summary Table ES-2 and, therefore, are not revisited here.

In case the surface water supply considered as part of the Off-site Water Facility Alternatives do not become available because of the required regulatory and legal approvals, the City conducted an analysis of optional sources of water other than the water supply evaluated as part of the Off-site Water Facility Alternatives. These optional water supplies are described and qualitatively evaluated in Section 3A.18.5. The analysis presented in Section 3A.18.5 is intended to satisfy the requirements of CEQA as part of the court in the case of *Vineyard Area Citizens for Responsible Growth, Inc. v. City of Rancho Cordova*, 40 Cal. 4th 412 (2007). This separation was considered necessary to distinguish the CEQA-required "*Vineyard* analysis" from the equal-level of detail for the "Land" and "Water" alternatives evaluated in Chapter 3 of this EIR/EIS per the requirements of NEPA.

IMPACT ANALYSIS

Impacts that would occur under each alternative development scenario are identified as follows: NP (No Project), NCP (No USACE Permit), PP (Proposed Project/Action), RIM (Resource Impact Minimization), CD (Centralized Development), and RHD (Reduced Hillside Development). The impacts for each alternative are compared relative to the PP at the end of each impact conclusion (i.e., similar, greater, lesser).

IMPACT 3A.18-1 Increased Demand for Water Supplies. *Project water demands would require the acquisition of surface water entitlements from the Natomas Central Mutual Water Company to provide a reliable water supply.*

On-Site Elements

NP

Under the No Project Alternative, development of up to 44 rural residences could occur under the existing Sacramento County agricultural zoning classification AG-80. There is currently no public water service available on the project site, and no off-site facilities would be constructed. Therefore, property owners under the No Project Alternative would be served by individual groundwater wells. Thus, the 44 individual rural residences that could be built under the No Project Alternative would not increase demand for surface water from a municipal water service provider and there would be **no direct** or **indirect** impacts related to increased demand for surface water supplies. Impacts associated with groundwater use from construction of individual wells on the rural residences under the No Project Alternative are evaluated in Section 3A.9, "Hydrology and Water Quality - Land." ***[Lesser]***

NCP

The discussion provided for the Proposed Project Alternative below would also generally apply to the No USACE Permit Alternative with water supplies consisting of CVP water purchased from NCMWC and conveyed to the Folsom SPA via one of the Off-site Water Facility Alternatives described in Chapter 2, "Alternatives." Table 3A.18-4 shows projected water demands for the No USACE Permit Alternative during normal, single-dry, and multiple-dry years in 5-year increments. The total projected water demands for the No USACE Permit Alternative at buildout are 4,198 AFY during normal years and 4,330 AFY during single-dry and multiple-dry years. The No Federal Action Alternative normal-year water demand would be 1,224 AFY and single-dry and multiple-dry years would be 1,247 AFY less than the Proposed Project Alternative.

The No USACE Permit Alternative's water demands under normal and critically dry year conditions were compared to available water supplies to determine whether a reliable water supply is available to serve the proposed project and existing water demands during normal and dry years. As shown in Table 3A.18-5, adequate water supplies are available to meet projected water demands under the No USACE Permit Alternative, even in critically-dry years.

Table 3A.18-4
Summary of Land Use and Water Demands for the No USACE Permit Alternative at Buildout

Land Use Type	Normal-Year Water Demands (AFY)[1]			Single-Dry and Multiple-Dry Year Water Demands (AFY)[2]		
	City of Folsom	EID	Total	City of Folsom	EID	Total
Single-Family	1,373	179	1,552	1,418	185	1,603
Single- Family High Density	452	--	452	462	--	462

Table 3A.18-5
Normal-Year and Dry-Year Comparison of Water Supply and Demand for the No USACE Permit Alternative

Surface Water Supply and Demand	Normal-Year	Dry-Year
Supply	6,000	6,000
Demand	4,198	4,330
Total surplus	**1,802**	**1,670**

Notes: AFY = acre-feet per year
Source: Tully & Young 2010

Based on the above analysis and as shown in Table 3.18-5, the City's proposed water supply, which is based on an assignment from NCMWC, is sufficient to meet projected water demands under the No Federal Action Alternative in normal and critically dry years. NCMWC water supplies are considered reliable, and, as a physical matter, there is reasonable certainty that surface water supplies needed to serve the No USACE Permit Alternative at buildout would be available. The City has already completed extensive consultation and coordination with pertinent entities including Reclamation, NCMWC, and SCWA to establish the initial framework for these approvals. It is assumed that once these entitlements are approved, the surface water supplies resulting from the NCMWC assignment would continue to flow to the City without interruption, barring a major shift in climate or policy, or unless current California water law principles are applied in a substantially more restrictive manner. However, given that the water supply cannot be secured and water conveyance and treatment facilities constructed in advance of approval of the project, without additional contingencies placed on the project applicants to confirm the availability of water and related infrastructure for the Folsom SPA, a **potentially significant direct** impact could result if no "Water" project were implemented in a timely manner following approval of the Specific Plan. ***[Lesser]***

Mitigation Measure: Implement Mitigation Measure 3A.18-1.

PP

Presently, there are no public water supply facilities on the "Land" portion of the project site. Approximately 3,330 acres of the "Land" portion of the project site would be within the City of Folsom's service area and the remaining 172 acres generally east of Empire Ranch Road would be within the El Dorado Irrigation District (EID) service area. It is assumed that the City would provide treated water to EID for its service area within the project site; however, water supplies delivered in EID's service area would be controlled by EID (Tully & Young 2010: 8). The water supply identified for the project is an entirely new source for both service areas and would therefore not affect any existing water supply operations in the City of Folsom or EID service areas (Tully & Young 2010: 7).

Proposed Project's Water Demand

In compliance with SB 610, a WSA has been prepared to determine whether the projected available water supplies would meet the Proposed Project's water demand, in addition to the existing and planned future uses. For purposes of calculating water supply and demand for the project, the WSA assumed water supplies would be required in 2013 and that implementation of the project would occur in five phases over a 20-year period (See Section 2.3.1, "Project Phasing" for further information on project phasing.).

The SPA's water demands at full buildout were estimated by applying water demand factors to each proposed land use. These demand factors were derived based on a review of meter data for the City of Folsom and other water purveyors in the region as well as pending conservation measures (Tully & Young 2010: 11). Water demands are assumed to increase by 5% from normal-year levels during single-dry and multiple-dry years as a result of increases in outdoor demands for all residential and nonresidential demand categories (Tully & Young 2010: 30). In addition, the total estimated water demands in normal, single-dry, and multiple-dry years assume a non-revenue water loss (i.e., water lost through leaks, meter inaccuracies, or unknown or unbilled connections and uses [e.g., fire hydrant flushing and construction water]) of 10%.

The project would conform to the 2007 requirements of Best Management Practices (BMPs) from the California Urban Water Conservation Memorandum of Understanding (or later edition if applicable). These BMPs could include: performing site-specific landscape and interior water surveys; conducting public information campaigns and school education programs; adopting a water waste ordinance; and identifying opportunities for installation of dedicated irrigation meters, monitoring progress through billing, and providing site-specific assistance for accounts 20% over budget. The California Urban Water Conservation BMPs would have a long-term affect on the City's ability to manage water use throughout the project site. To the extent that the City requires installation of

dedicated irrigation meters in the project site, a monitoring and survey program would provide an opportunity to ensure that landscape water demands are achieving desired water conservation targets. The City's water conservation coordinator would be assigned to manage water conservation programs and City staff will be authorized to enforce the water waste ordinance. Through targeted outreach, the City can encourage continued customer use of highly efficient appliances and irrigation systems, emphasize the need to retain efficient landscape plantings, and minimize otherwise wasteful uses. (Tully & Young 2010: 19).

As of 2009, urban water suppliers are required to select one of four water conservation targets with the statewide goal of achieving a 20% reduction in urban per capita water use by 2020. While the City has yet to select a water conservation target, the city intends to select a target that would require the City to reduce water use by 20% by 2020. (Tully & Young 2010: 15.)

The WSA assumes that a 20% reduction in total demand is a long-term citywide goal. In the near term, it is assumed the City's water conservation efforts related to efficient infrastructure requirements and landscape features support at least a 10% reduction in historic per capita unit demand factors. (Tully & Young 2010: 15.)

Table 3A.18-6 shows projected water demands for the Proposed Project during normal, single-dry, and multiple-dry years. The total projected water demands for the Proposed Project at buildout are 5,422 AFY during normal years and 5,577 AFY during single-dry and multiple-dry years.

Table 3A.18-6
Summary of Land Use and Water Demands for the Proposed Project Alternative at Buildout

Land Use Type	Normal-Year Water Demands (AFY) [1]			Single-Dry and Multiple-Dry Year Water Demands (AFY) [2]		
	City of Folsom	EID	Total	City of Folsom	EID	Total
Single Family	1,028	69	1,097	1,061	71	1,132
Single-Family High Density	1,108	69	1,177	1,132	70	1,202
Multi-family Low Density	556	65	621	567	66	633
Multi-family Medium Density	249	--	249	252	--	252
Multi-family High Density	247	--	247	249	--	249

Circulation Improvements	68	3	71	72	3	75
Open Space	--	--	--	--	--	--
Total Demand	**5,166**	**255**	**5,422**	**5,315**	**262**	**5,577**

Notes: AFY = acre-feet per year

[1] The total estimated water demand in a normal year assumes a 10% non-revenue water factor.

[2] The total estimated water demand in single and multiple dry years assumes an increase of 5% for outdoor water demands and then applies a 10% non-revenue water factor.

[3] The Mixed-Use District assumes residential and commercial land uses.

[4] Minor discrepancies in totals are a result of rounding.

Source: Tully & Young 2010: 31

Proposed Water Supply

Water demands for the project would be met by securing a permanent assignment of long-term, CVP "Project Water" from the NCMWC under Contract No. 14-06-200-885A-R-1 (NCMWC CVP Contract) with the Bureau of Reclamation (Tully & Young 2010: 33). The normal year supply contractually available to the City would be not less than 8,000 AFY; however, the maximum diversion would be 6,000 AFY (Tully & Young 2010: 43). This higher quantity of water is required to factor in the 25% reduction that could occur in single-dry and multiple-dry years thereby reducing the quantity delivered to 6,000 AFY.

The "Project Water" would be made available by NCMWC reducing its surface water diversions/pumping during the irrigation season at the Riverside Pumping Plant. This water supply would then remain in the Sacramento River and would flow approximately 20 miles downstream, where it would be removed from the river at the FRWA's diversion facility. This diverted surface water would be conveyed to the project site via both FRWA diversion facilities and the off-site conveyance facilities that are proposed as part of the "Water" portion of this project. (See Chapter 2, "Alternatives" of this DEIR/DEIS for a detailed description of the proposed off-site water facilities.) The water may be either treated by SCWA's Vineyard Surface WTP or through construction of a different WTP proposed as part of the "Water" portion of this project (see Chapter 2, "Alternatives" and Impact 3A.18-2 below).

The CVP "Project Water," by contract, is currently limited to use for irrigation during the growing season (July and August) in the NCMWC service area. The water rights permits issued to the Bureau of Reclamation by the SWRCB include M&I as a permitted use. Therefore, CVP "Project Water" can be used for M&I purposes within the project site.

For the CVP "Project Water" to serve as an effective water supply, it would be necessary for Bureau of Reclamation to modify the existing delivery schedule to a year-round M&I schedule, which would allow for a more consistent diversion of 6,000 AFY of the 8,000 AFY over the course of a given year.

Discretionary approval from the Bureau of Reclamation would be required for the use of CVP "Project Water" for M&I purposes and for modification of the existing delivery schedule. The City would be responsible for obtaining approvals from the Bureau of Reclamation. The City is serving as the lead agency under CEQA. The Bureau of Reclamation is a NEPA cooperating agency in relation to this project and would be required to comply with all applicable ESA requirements.

Water Supply Agreements

Surface water would be obtained from the NCMWC pursuant to a series of agreements between South Folsom Properties LLC (SFP) and NCMWC, the City and SFP, and the City and SCWA.

SFP and NCMWC Agreement

The SFP and NCMWC have executed *Terms and Conditions of Purchase and Sale of Water Entitlements* on December 17, 2007 for the initial purchase and sale of surface water from NCMWC (see Appendix E of the WSA).Under the SFP-NCMWC Agreement, NCMWC has agreed to permanently assign to the City, through SFP, not less than 8,000 AFY of CVP "Project Water" to which NCMWC has rights under its Renewal Contract with the Bureau of Reclamation and provides that the assigned water will be subject to a 25% reduction in a "Critical Year." The agreement identifies the conditions that are required by both parties to finalize the sale, which will ultimately lead to a permanent assignment of CVP "Project Water" to the City (see City of Folsom-SFP MOU, below). (Tully & Young 2010: 38).

The SFP-NCMWC Agreement is effective until April 1, 2012, unless extended by SFP. During the period that the SFP-NCMWC Agreement is effective, both SFP and NCMWC must satisfy specific obligations to ensure that water can ultimately be made available for use as a M&I supply. Those obligations include: (1) preparation of an

engineering study to ensure NCMWC may meet its future demands in the absence of the assigned su
approval from the Bureau of Reclamation to reschedule the assigned supply from an irrigation dema le
to a M&I schedule; and (3) completion of all state and federal environmental review. (Tully & Your 9.)

City of Folsom and SFP Agreement

The City of Folsom and SFP executed a non-binding MOU on August 26, 2008, which contemplates the assignment to the City of NCMWC water supplies acquired under the SFP-NCMWC Agreement (see Appendix F of the WSA). The MOU requires the City to evaluate the technical feasibility of delivering water on a year-round M&I schedule, diverting water from the Sacramento River at the FRWA facilities, and conveying water to the project site using FRWA facilities. The City and SFP cannot sign a binding legal agreement until after the environmental review is completed. (Tully & Young 2010: 39.)

City of Folsom and SCWA Capacity Agreement

The City of Folsom and the SCWA signed the *Memorandum of Understanding between the City of Folsom and Sacramento County Water Agency Concerning the Folsom Sphere of Influence Area and Sharing of Freeport Project Capacity* on December 15, 2009 (see Appendix M3). The MOU establishes principles and parameters to govern negotiations between the City and SCWA for purchase of a portion of SCWA's capacity in FRWA's diversion facilities for conveyance of NMCWC water to the project site. The City and SCWA will cooperate during the MOU's term limits with the goal of eventually executing a binding agreement. (Tully & Young 2010: 39.)

Reasonable Likelihood of Water Supplies to Meet Project Demands

It is the intent of the City of Folsom to obtain 8,000 AFY surface water from NCMWC. In each single-dry and multiple-dry years, it is assumed that the water supply is restricted by 25% resulting in a total supply of 6,000 AFY. Although 8,000 AFY is anticipated to be available through contract, for every normal water year between 2013 and 2033, the City would divert a maximum of 6,000 AFY to serve the project. (Tully & Young 2010: 45.)

The Proposed Project Alternative's water demands under normal and critically dry year conditions were compared to available water supplies to determine whether a reliable water supply is available to serve the Proposed Project and existing water demands during normal and dry years. As shown in Table 3A.18-7, adequate water supplies are available to meet projected water demands of the Proposed Project, even in critically-dry years.

Table 3A.18-7
Normal-Year and Dry-Year Comparison of Water Supply and Demand for the Proposed Project Alternative

Surface Water Supply and Demand	Normal-Year	Dry-Year
Supply	6,000	6,000
Demand	5,421	5,577
Total surplus	**579**	**423**

Notes: AFY = acre-feet per year
Source: Tully & Young 2010: 46

Impact Conclusion

Based on the above analysis and as shown in Table 3A.18-7, the proposed water supply from NCMWC would be sufficient to meet projected water demands under the Proposed Project Alternative in normal and critically dry

years. Those water supplies are considered reliable, and, as a physical matter, there is reasonable certainty that surface water supplies needed to serve the Proposed Project Alternative at buildout would be available. Although there is no complete certainty as to the legal and regulatory approvals required for the "Water" portion of the project or Off-site Water Facility Alternatives, including those from Reclamation and SCWA; the draft agreements and MOUs entered into between the City and/or project applicants and some of these critical approval entities (see Appendix M-I, M-II, and M-III) establish a solid initial framework for these approvals. This fact combined with the development the City's proposed Off-site Water Facility Alternatives as presented in Chapter 2, "Alternative" provide a high level of certainty for the reliability of the proposed CVP water supply, conveyance mechanisms, and water treatment capacity. Based on these circumstances, the project would have sufficient water supplies available to serve projected demand from CVP water supplies acquired as part of the City's Off-site Water Facility Alternatives and, therefore, the **direct** and **indirect** impacts of an insufficient water supply for the project are considered **less-than-significant**. ***[Similar]***

Indirect impacts from use of NCMWC surface water supplies to meet project demand, SCWA's dedication of up to 6.5 mgd in Segments 1 and 2 in the Freeport Project, and effects of changing the delivery CVP schedule from agriculture to M&I are evaluated throughout the "B", or "Water" sections of Chapter 3 and Chapter 4, "Other Statutory Requirements" contained in this DEIR/DEIS. It is assumed that once these entitlements are approved, the surface water supplies would continue to flow to City through the Freeport Project without interruption, barring a major shift in climate or policy, or unless current California water law principles are applied in a substantially more restrictive manner. However, given that the water supply cannot be secured and water conveyance and treatment facilities constructed in advance of approval of the project, without additional contingencies placed on the project applicants to confirm the availability of water and related infrastructure for the Folsom SPA, a **potentially significant direct** impact could result if no "Water" Project were implemented in a timely manner following approval of the Specific Plan. ***[Similar]***

Mitigation Measure 3A.18-1: Submit Proof of Surface Water Supply Availability.

a. Prior to approval of any small-lot tentative subdivision map subject to Government Code Section 66473.7 (SB 221), the City shall comply with that statute. Prior to approval of any small-lot tentative subdivision map for a proposed residential project not subject to that statute, the City need not comply with Section 66473.7, or formally consult with any public water system that would provide water to the affected area; nevertheless, the City shall make a factual showing or impose conditions similar to those required by Section 66473.7 to ensure an adequate water supply for development authorized by the map.

b. Prior to recordation of each final subdivision map, or prior to City approval of any similar project-specific discretionary approval or entitlement required for nonresidential uses, the project applicant(s) of that project phase or activity shall demonstrate the availability of a reliable and sufficient water supply from a public water system for the amount of development that would be authorized by the final subdivision map or project-specific discretionary nonresidential approval or entitlement. Such a demonstration shall consist of information showing that both existing sources are available or needed supplies and improvements will be in place prior to occupancy.

Implementation: The project applicant(s) of all project phases.

Timing: Before approval of final maps and issuance of building permits for any project phases.

Enforcement: City of Folsom Community Development Department and City of Folsom Public Works Department.

The discussion provided for the Proposed Project Alternative would also generally apply to the Resource Impact Minimization alternative with water supplies consisting of CVP water purchased from NCMWC and conveyed to the Folsom SPA via one of the Off-site Water Facility Alternatives described in Chapter 2, "Alternatives." Table 3A.18-8 shows projected water demands for the Resource Impact Minimization Alternative during normal, single-dry, and multiple-dry years. The total projected water demands for the Resource Impact Minimization Alternative at buildout are 4,449 AFY during normal years and 4,580 AFY during single-dry and multiple-dry years. The Resource Impact Minimization Alternative normal-year water demand would be 973 AFY less and single-dry and multiple-dry years would be 997 AFY less than the Proposed Project Alternative.

Water demands for the project would be met by securing a permanent assignment of long-term, CVP "Project Water" from the NCMWC under Contract No. 14-06-200-885A-R-1 (NCMWC CVP Contract) with the Bureau of Reclamation (Tully & Young 2010: 33). The normal year supply contractually available to the City would be not less than 8,000 AFY; however, the maximum diversion would be 6,000 AFY (Tully & Young 2010: 43). This higher quantity of water is required to factor in the 25% reduction that could occur in single-dry and multiple-dry years thereby reducing the quantity delivered to 6,000 AFY.

Table 3A.18-8
Summary of Land Use and Water Demands for the Resource Impact Minimization Alternative at Buildout

Land Use Type	Normal-Year Water Demands (AFY) [1]			Single-Dry and Multiple-Dry Year Water Demands (AFY) [2]		
	City of Folsom	EID	Total	City of Folsom	EID	Total
Single-Family	878	106	984	906	109	1,015
Single- Family High Density	1,023	62	1,085	1,045	63	1,108
Multifamily Low Density	564	--	564	575	--	575
Multifamily Medium Density	192	--	192	194	--	194
Multifamily High Density	57	--	57	57	--	57

Circulation Improvements	60	2	62	63	2	65
Open Space	--	--	--	--	--	--
Total Demand [4]	**4,238**	**210**	**4,449**	**4,363**	**217**	**4,580**

Notes: AFY = acre-feet per year

[1] The total estimated water demand in a normal year assumes a 10% non-revenue water factor.

[2] The total estimated water demand in single and multiple dry years assumes an increase of 5% for outdoor water demands and then applies a 10% non-revenue water factor.

[3] The Mixed-Use District assumes residential and commercial land uses.

[4] Minor discrepancies in totals are a result of rounding.

Source: Tully & Young 2010; AECOM, 2010

The Resource Impact Minimization Alternative's water demands under normal and critically dry year conditions were compared to available water supplies to determine whether a reliable water supply is available to serve the project and existing water demands during normal and dry years. As shown in Table 3A.18-9, adequate water supplies are available to meet projected water demands of the project under the Resource Impact Minimization Alternative, even in critically-dry years.

Table 3A.18-9
Normal-Year and Dry-Year Comparison of Water Supply and Demand for the Resource Impact Minimization Alternative

Surface Water Supply and Demand	Normal-Year	Dry-Year
Supply	6,000	6,000
Demand	4,449	4,580
Total surplus	**1,551**	**1,420**

Notes: AFY = acre-feet per year
Source: Tully & Young 2010

Based on the above analysis and as shown in Table 3A.18-8, NCMWC has surface water supplies available to meet projected water demands under the Resource Impact Minimization Alternative in normal and critically dry years. The proposed NCMWC water supply is considered reliable, and, as a physical matter, there is reasonable certainty that surface water supplies needed to serve the Resource Impact Minimization Alternative at buildout would be available. The City has already completed extensive consultation and coordination with pertinent entities including Reclamation, NCMWC, and SCWA to establish the initial framework for these approvals. It is assumed that once the necessary approvals are secured, the surface water supplies would continue to flow to NCMWC without interruption, barring a major shift in climate or policy, or unless current California water law principles are applied in a substantially more restrictive manner. However, given that the water supply cannot be secured and water conveyance and treatment facilities constructed in advance of approval of the project, without additional contingencies placed on the project applicants to confirm the availability of water and related infrastructure for the Folsom SPA, a **potentially significant direct** impact could result if no "Water" project were implemented in a timely manner following approval of the Specific Plan. ***[Lesser]***

Mitigation Measure: Implement Mitigation Measure 3A.18-1.

CD

The discussion provided for the Proposed Project Alternative would also generally apply to the Centralized Development Alternative with water supplies consisting of CVP water purchased from NCMWC and conveyed to the Folsom SPA via one of the Off-site Water Facility Alternatives described in Chapter 2, "Alternatives." Table 3A.18-109 shows projected water demands for the Centralized Development Alternative during normal, single-dry, and multiple-dry years. The total projected water demands for the Centralized Development Alternative at buildout are 4,606 AFY during normal years and 4,737 AFY during single-dry and multiple-dry years. The Centralized Development Alternative normal-year water demand would be 816 AFY less and single-dry and multiple-dry years would be 840 AFY less than the Proposed Project Alternative.

Table 3A.18-10
Summary of Land Use and Water Demands for the Centralized Development Alternative at Buildout

Land Use Type	Normal-Year Water Demands (AFY) [1]			Single-Dry and Multiple-Dry Year Water Demands (AFY) [2]		
	City of Folsom	EID	Total	City of Folsom	EID	Total
Single-Family	417	--	417	430	--	430

Total Demand [4]	**4,566**	**41**	**4,606**	**4,694**	**42**	**4,737**

Notes: AFY = acre-feet per year
[1] The total estimated water demand in a normal year assumes a 10% non-revenue water factor.
[2] The total estimated water demand in single and multiple dry years assumes an increase of 5% for outdoor water demands and then applies a 10% non-revenue water factor.
[3] The Mixed-Use District assumes residential and commercial land uses.
[4] Minor discrepancies in totals are a result of rounding.
Source: Tully & Young 2010; AECOM, 2010

The Centralized Development Alternative's water demands under normal and critically dry year conditions were compared to available water supplies to determine whether a reliable water supply is available to serve the project and existing water demands during normal and dry years. As shown in Table 3A.18-11, adequate water supplies are available to meet projected water demands of the Centralized Development Alternative, even in critically-dry years.

Table 3A.18-11
Normal-Year and Dry-Year Comparison of Water Supply and Demand for the Centralized Development Alternative

Surface Water Supply and Demand	Normal-Year	Dry-Year
Supply	6,000	6,000
Demand	4,606	4,737
Total surplus	**1,394**	**1,263**

Notes: AFY = acre-feet per year
Source: Tully & Young 2010

Based on the above analysis and as shown in Table 3A.18-10, the proposed water supply to be assigned by NCMWC would be sufficient to meet projected water demands under the Centralized Development Alternative in normal and critically dry years. NCMWC water supplies are considered reliable, and, as a physical matter, there is reasonable certainty that surface water supplies needed to serve the Centralized Development Alternative at buildout would be available. The City has already completed extensive consultation and coordination with pertinent entities including Reclamation, NCMWC, and SWCA to establish the initial framework for these approvals. It is assumed that once these entitlements are approved, the surface water supplies would continue to flow to the City without interruption, barring a major shift in climate or policy, or unless current California water law principles are applied in a substantially more restrictive manner. However, given that the water supply cannot be secured and water conveyance and treatment facilities constructed in advance of approval of the project, without additional contingencies placed on the project applicants to confirm the availability of water and related infrastructure for the Folsom SPA, a **potentially significant direct** impact could result if no "Water" project were implemented in a timely manner following approval of the Specific Plan.***[Lesser]***

Mitigation Measure: Implement Mitigation Measure 3A.18-1.

RHD

The discussion provided for the Proposed Project Alternative would also generally apply to the Reduced Hillside Density Alternative with water supplies consisting of CVP water purchased from NCMWC and conveyed to the Folsom SPA via one of the Off-site Water Facility Alternatives described in Chapter 2, "Alternatives." The WSA prepared per the requirements of SB 610 for the Proposed Project also includes a separate determine whether the projected available water supplies would meet the Reduced Hillside Development Alternative's water demand, in addition to the existing and planned future uses. This alternative was included within the WSA because the density of development under the Reduced Hillside Development Alternative is higher than under the Proposed Project. However, as described in detail in Chapter 2, "Alternatives," the Reduced Hillside Development Alternative would include a variety of water conservation strategies that are not included in the Proposed Project.

Table 3A.18-12 shows projected water demands for the Reduced Hillside Development Alternative during normal, single-dry, and multiple-dry years. The total projected water demands for the Reduced Hillside Development Alternative at buildout are 5,395 AFY during normal years and 5,547 AFY during single-dry and multiple-dry years. The Reduced Hillside Development Alternative normal-year water demand would be 27 AFY less and single-dry and multiple-dry years would be 30 AFY less than the Proposed Project Alternative.

Table 3A.18-12
Summary of Land Use and Water Demands for the Reduced Hillside Development Alternative at Buildout

Land Use Type	Normal-Year Water Demands (AFY) [1]			Single-Dry and Multiple-Dry Year Water Demands (AFY) [2]		
	City of Folsom	EID	Total	City of Folsom	EID	Total

Notes: AFY = acre-feet per year

[1] The total estimated water demand in a normal year assumes a 10% non-revenue water factor.

[2] The total estimated water demand in single and multiple dry years assumes an increase of 5% for outdoor water demands and then applies a 10% non-revenue water factor.

[3] The Mixed-Use District assumes residential and commercial land uses.

[4] Minor discrepancies in totals are a result of rounding.

Source: Tully & Young 2010: 31

The Reduced Hillside Development Alternative's water demands under normal and critically dry year conditions were compared to available water supplies to determine whether a reliable water supply is available to serve the project and existing water demands during normal and dry years. As shown in Table 3A.18-13, adequate water supplies are available to meet projected water demands of the Reduced Hillside Development Alternative, even in critically-dry years.

Table 3A.18-13
Normal-Year and Dry-Year Comparison of Water Supply and Demand for the Reduced Hillside Development Alternative

Surface Water Supply and Demand	Normal-Year	Dry-Year
Supply	6,000	6,000
Demand	5,395	5,547
Total surplus	**605**	**453**

Notes: AFY = acre-feet per year

Source: Tully & Young 2010

Based on the above analysis and as shown in Table 3A.18-13, the proposed water supply to be assigned by NCMWC is sufficient to meet projected water demands under the Reduced Hillside Development Alternative in normal and critically dry years. This supply is considered reliable, and, as a physical matter, there is reasonable certainty that surface water supplies needed to serve the Reduced Hillside Development Alternative at buildout would be available. The City has already completed extensive consultation and coordination with pertinent entities including Reclamation, NCMWC, and SCWA to establish the initial framework for these approvals. It is assumed that once these entitlements are approved, the surface water supplies would continue to flow to the City without interruption, barring a major shift in climate or policy, or unless current California water law principles are applied in a substantially more restrictive manner. However, given that the water supply cannot be secured and water conveyance and treatment facilities constructed in advance of approval of the project, without additional contingencies placed on the project applicants to confirm the availability of water and related

infrastructure for the Folsom SPA, a **potentially significant direct** impact could result if no "Water" project were implemented in a timely manner following approval of the Specific Plan. ***[Lesser]***

Mitigation Measure: Implement Mitigation Measure 3A.18-1.

Off-Site Elements

The water conveyance and storage facilities evaluated throughout the "B", or "Water" sections of Chapter 3 of this DEIR/DEIS would provide the necessary infrastructure needed to provide on-site water service to the SPA, and construction of the off-site freeway interchange improvements, sewer force main, and the detention basin in Sacramento County, and the two roadway connections into El Dorado Hills, would not involve construction of new housing or development of new businesses that would increase demand for water supply. Therefore, the off-site elements related to the "Land" portion of the project would have a **direct, less-than-significant** impact on the demand water supply. The **indirect** physical impacts of constructing the on-site water conveyance and storage facilities are addressed throughout this EIR/EIS in connection with discussions of the impacts of overall site development. ***[Similar]***

Mitigation Measure: No mitigation measures are required.

This project includes a water supply to serve the proposed development of the SPA. Implementation of Mitigation Measure 3A.18-1 therefore would reduce significant impacts related to the need for surface water supplies sunder the No USACE Permit, Proposed Project, Resource Impact Minimization, Centralized Development, and Reduced Hillside Development Alternatives to a **less-than-significant** level because the City would require written certification verifying the availability of a long-term, reliable surface water supply for the project or would require that needed improvements be in place prior to occupancy.

IMPACT 3A.18-2 Increased Demand for Off-Site Water Conveyance and Treatment Facilities. *Project implementation would result in increased demand for off-site water treatment facilities to deliver water to customers on the project site.*

On-Site Elements

NP

Under the No Project Alternative, development of up to 44 rural residences could occur under the existing Sacramento County agricultural zoning classification AG-80. No off-site water facilities would be constructed, and there is currently no public water service available on the project site. Therefore, property owners under the No Project Alternative would be served by individual groundwater wells. Thus, the 44 individual rural residences that could be built under the No Project Alternative would not increase demand for municipal water conveyance facilities and there would be **no direct** or **indirect** impacts. Impacts associated with groundwater use from construction of individual wells on the rural residences under the No Project Alternative are evaluated in Section 3A.9, "Hydrology and Water Quality - Land." ***[Lesser]***

PP, RIM, CD, RHD, NF

Surface water would be diverted from the Sacramento River at FRWA's diversion facilities and conveyed to the SPA via both FRWA diversion facilities and the off-site conveyance facilities proposed in the "Water" portion of this DEIR/DEIS. (See Chapter 2, "Alternatives," for a detailed discussion of off-site conveyance pipeline alternatives and off-site WTP alternatives.)

The project would include purchasing from SCWA dedicated capacity within the FRWP, which would serve as the point of diversion on the Sacramento River and partial conveyance pathway for not more than 6,000 AFY of

CVP "Project Water" purchased from NCMWC. CVP "Project Water" would be pumped and conveyed through the FRWA diversion facilities and conveyance pipeline to the SCWA and EBMUD pipeline bifurcation point. New off-site water supply conveyance infrastructure would be constructed from the bifurcation point to the project site. (The impacts of constructing this new water supply conveyance infrastructure are evaluated throughout the "B", or "Water" sections of Chapter 3 of this DEIR/DEIS.)

As discussed above, the City and SCWA have entered into a MOU to develop conditions under which the City may convey surface water using SCWA's capacity, with the goal of eventually executing a binding agreement. (Tully & Young 2010: 39). Under this agreement, the City would purchase 6.5 mgd of dedicated capacity within the SCWA's 85 mgd portion of the FRWA's diversion facilities. This MOU would also allow for additional capacity to accommodate peaking conditions of up to 10 mgd. The use of this capacity would not increase SCWA's permitted diversion rates and would not require any increase in the FRWP's currently permitted diversion capacity. For this reason, no physical changes to the FRWP diversion and pump structure and conveyance pipeline would occur.

One raw or treated-water booster pumping station would need to be constructed at the connection with the Freeport Project to provide sufficient operating pressure within the force main. Depending on the water treatment option chosen, the connection point would occur at the Vineyard Surface WTP, some point along SCWA's proposed northern service area pipeline, or the existing Douglas Treated-Water Storage Tanks. The number and type of pumps would depend on detailed design criteria and the precise location for the pump station has not been selected. However, the City anticipates that this facility would be in close proximity to the associated connection point to the FRWA diversion facilities.

Water treatment could be provided either through purchasing 10-mgd capacity within the Vineyard Surface WTP, construction of a 10-mgd White Rock WTP located southeast of the intersection of White Rock Road and Prairie City Road, construction of a 10-mgd Folsom Boulevard WTP located south of Folsom Boulevard, or construction of a 10-mgd WTP located on the Folsom South of U.S. 50 project site (see Exhibit 2-3, in Chapter 2, "Alternatives").

Because the "Land" portion of the project site is not served by a public water system and sufficient off-site water conveyance and treatment facilities necessary to serve the project have not been constructed, and because the City and SCWA have not entered into a binding agreement for use of FRWA diversion facilities, this is considered a **direct, potentially significant** impact. The **indirect** physical impacts of constructing these water conveyance and treatment facilities are addressed throughout this EIR/EIS in the "B", or "Water" sections of Chapter 3 and in Chapter 4, "Other Statutory Requirements." ***[Similar]***

> Mitigation Measure 3A.18-2a: Submit Proof of Adequate Off-Site Water Conveyance Facilities and Implement Off-Site Infrastructure Service System or Ensure That Adequate Financing Is Secured.
>
> Before the approval of the final map and issuance of building permits for all project phases, the project applicant(s) of all project phases shall submit proof to the City of Folsom that an adequate off-site water conveyance system either has been constructed or is ensured or other sureties to the City's satisfaction. The off-site water conveyance infrastructure sufficient to provide adequate service to the project shall be in place for the amount of development identified in the tentative map before approval of the final map and issuance of building permits for all project phases, or their financing shall be ensured to the satisfaction of the City.
>
> **Implementation:** The project applicant(s) of all project phases.
>
> **Timing:** Before approval of final maps and issuance of building permits for any project phases.

Enforcement: City of Folsom Community Development Department and City of Folsom Public Works Department.

Mitigation Measure 3A.18-2b: Demonstrate Adequate Off-Site Water Treatment Capacity (if the Off-Site Water Treatment Plant Option is Selected).

If an off-site water treatment plant (WTP) alternative is selected (as opposed to the on-site WTP alternative), the project applicant(s) of all project phases shall demonstrate adequate capacity at the off-site WTP. This shall involve preparing a tentative map–level study and paying connection and capacity fees as determined by the City. Approval of the final project map shall not be granted until the City verifies adequate water treatment capacity either is available or is certain to be available when needed for the amount of development identified in the tentative map before approval of the final map and issuance of building permits for all project phases.

Implementation: The project applicant(s) of all project phases.

Timing: Before approval of final maps and issuance of building permits for any project phases.

Enforcement: City of Folsom Community Development Department and City of Folsom Public Works Department.

Off-Site Elements

The off-site water conveyance and treatment facilities would provide the necessary infrastructure needed to provide water service to the project site, and construction of the off-site freeway interchange improvements, sewer force main, detention basin, and the two roadway connections into El Dorado Hills would not involve construction of new housing or development of new businesses that would increase demand for water conveyance and treatment facilities. Therefore, the off-site elements required for the "Land" portion of the project would have a **direct, less-than-significant** impact on the demand additional off-site water conveyance and treatment facilities. The **indirect** physical impacts of constructing the on-site water conveyance and storage facilities are addressed throughout this EIR/EIS in the "B", or "Water" sections of Chapter 3 and in Chapter 4, "Other Statutory Requirements". ***[Similar]***

Mitigation Measure: No mitigation measures are required.

Implementation of Mitigation Measures 3A.18-2a and 3A.18-2b would reduce significant impacts associated with increased demand for off-site water conveyance and treatment facilities under the No USACE Permit, Proposed Project, Resource Impact Minimization, Centralized Development, and Reduced Hillside Development Alternatives to a **less-than-significant** level because adequate off-site water conveyance and treatment facilities would be documented or adequate financing would be secured before approval final maps and issuance of building permits.

3A.18.4 RESIDUAL SIGNIFICANT IMPACTS

Implementation of mitigation measures contained in this section would reduce impacts associated with increased demand for potable water supply and conveyance and treatment facilities to a **less-than-significant** level by ensuring the provision of adequate water supplies and construction of sufficient conveyance and treatment capacity in advance of approval of individual development applications with the Folsom SPA. This conclusion is supported by the fact that this project includes a water supply that, when implemented, would be sufficient to satisfy the water demands of the proposed SPA development. Therefore, no residual significant impacts would occur.

3A.18.5 WATER SUPPLY OPTIONS TO LONG-TERM WATER SUPPLY

The water supply analysis in a CEQA document is governed by California case law that requires the lead agency to consider both the relative certainty of new water supplies that a project would require and the impacts that could result from the use of those new water supplies. The following discussion introduces the principles governing water supply analyses in CEQA documents and distinguishes between the analysis of the certainty of supplies and the impact of providing those supplies. These principles are as follows:

1. An environmental impact report (EIR) may not assume a solution to problems of water supply, but must instead present sufficient facts to evaluate the pros and cons of supplying the required water. (*Santiago County Water District v. Orange* [1981] 118 Cal.App.3d 818, 829.)

2. The water supply analysis for large, multiphase projects may not be limited to the first few years or phases. Furthermore, the first or programmatic document for such a project may not defer analysis to future phases, but must analyze reasonably foreseeable impacts of supplying required water. The tiering principle does not allow deferral to future studies or documents. (*Santa Clarita Organization for Planning the Environment v. County of Los Angeles* [2003] 106 Cal. App. 4th 715, 723.)

3. An EIR evaluating a planned land use project must assume that all phases of the project will eventually be built and will need water. The EIR for such a project must analyze the impacts of supplying water to the entire project. (*Stanislaus Natural Heritage Project v. County of Stanislaus* [1996] 48 Cal.App.4th 182, 206.)

4. Future water supplies for a project must bear a reasonable likelihood of proving to be available. While absolute certainty is not required, water supplies must be identified with more specificity as projects progress from general to specific phases (*Vineyard Area Citizens for Responsible Growth, Inc. v. City of Rancho Cordova* [2007] 40 Cal. 4th, 412, 434). "Where, despite a full discussion, it is impossible to confidently determine that anticipated water sources will be available, CEQA requires some discussion of possible replacement sources or alternative to use of the anticipated water, and of the environmental consequences of those contingencies." (*Vineyard Area Citizens for Responsible Growth, Inc. v. City of Rancho Cordova* [2007] 40 Cal. 4th 412, 432.)

5. Although much of the case law focuses on the issue of certainty, the ultimate issue under CEQA is not whether an EIR establishes a likely source of water, but whether the document adequately analyzes the reasonably foreseeable impacts of supplying water to the project. (*Vineyard Area Citizens for Responsible Growth, Inc. v. City of Rancho Cordova* [2007] 40 Cal. 4th, 412, 434.)

The WSA concluded that the water supply that the City would acquire from NCMWC would meet projected water demands in normal and critically dry years, and it is reasonably certain as a physical matter that the surface water supplies could be delivered to the SPA in the amounts needed to serve the Proposed Project Alternative at buildout. However, there is no similar reasonable certainty from a legal and regulatory standpoint, since additional actions by the Bureau of Reclamation and SCWA would be necessary. Therefore, in case the surface water supplies do not become available because of the required regulatory and legal approvals, an analysis of optional sources of water in addition to the City's proposed water supply is provided below as required by the court in the case of *Vineyard Area Citizens for Responsible Growth, Inc. v. City of Rancho Cordova*, 40 Cal. 4th 412 (2007).

The following "Water Supply Options" have been developed and are evaluated herein:

- Option 1 – Groundwater from the Central Sacramento Groundwater Basin
- Option 2 – Other Senior Sacramento River Water Right Holders
- Option 3 – Conservation of Existing City Supplies and Water System Retrofit

The discussion and assessment of these Water Supply Options in this section follows the principles identified above. Accordingly, this analysis evaluates both the certainty of optional water supplies and provides a qualitative assessment of the impacts that could result from the use of those supplies commensurate with the requirements of CEQA. An impact is considered significant if the water supply option would result in a potential water shortage or another significant adverse physical impact on the environment. To facilitate a meaningful comparison between the water supply options and the Off-site Water Facility Alternatives, an indication is also provided as to whether the Water Supply Option would result in greater, lesser, or similar impacts to the Proposed Off-site Water Facility Alternative.

Option 1 - Groundwater from the Central Sacramento Groundwater Basin

Under water supply Option 1, the City would serve potable water demands within the SPA using groundwater supplies from the South American Groundwater Sub-basin; also locally referred to as the Central Sacramento Groundwater Basin. The existing Central Sacramento County Groundwater Management Plan (CSCGMP), dated February 2006, estimates the central groundwater basin's long-term sustainable yield at 273,000 AFY (CSCGMP, 2006). This value is based on the results of the Water Forum Agreement, which is described in more detail in Sections 3B.9, "Hydrology and Water Quality - Water," and 3B.17, "Groundwater – Water." Existing documentation, including the CSCGMP, suggests that between 20,000 to 40,000 AFY of groundwater supply remains available within the basin under existing conditions without exceeding the sustainable yield.

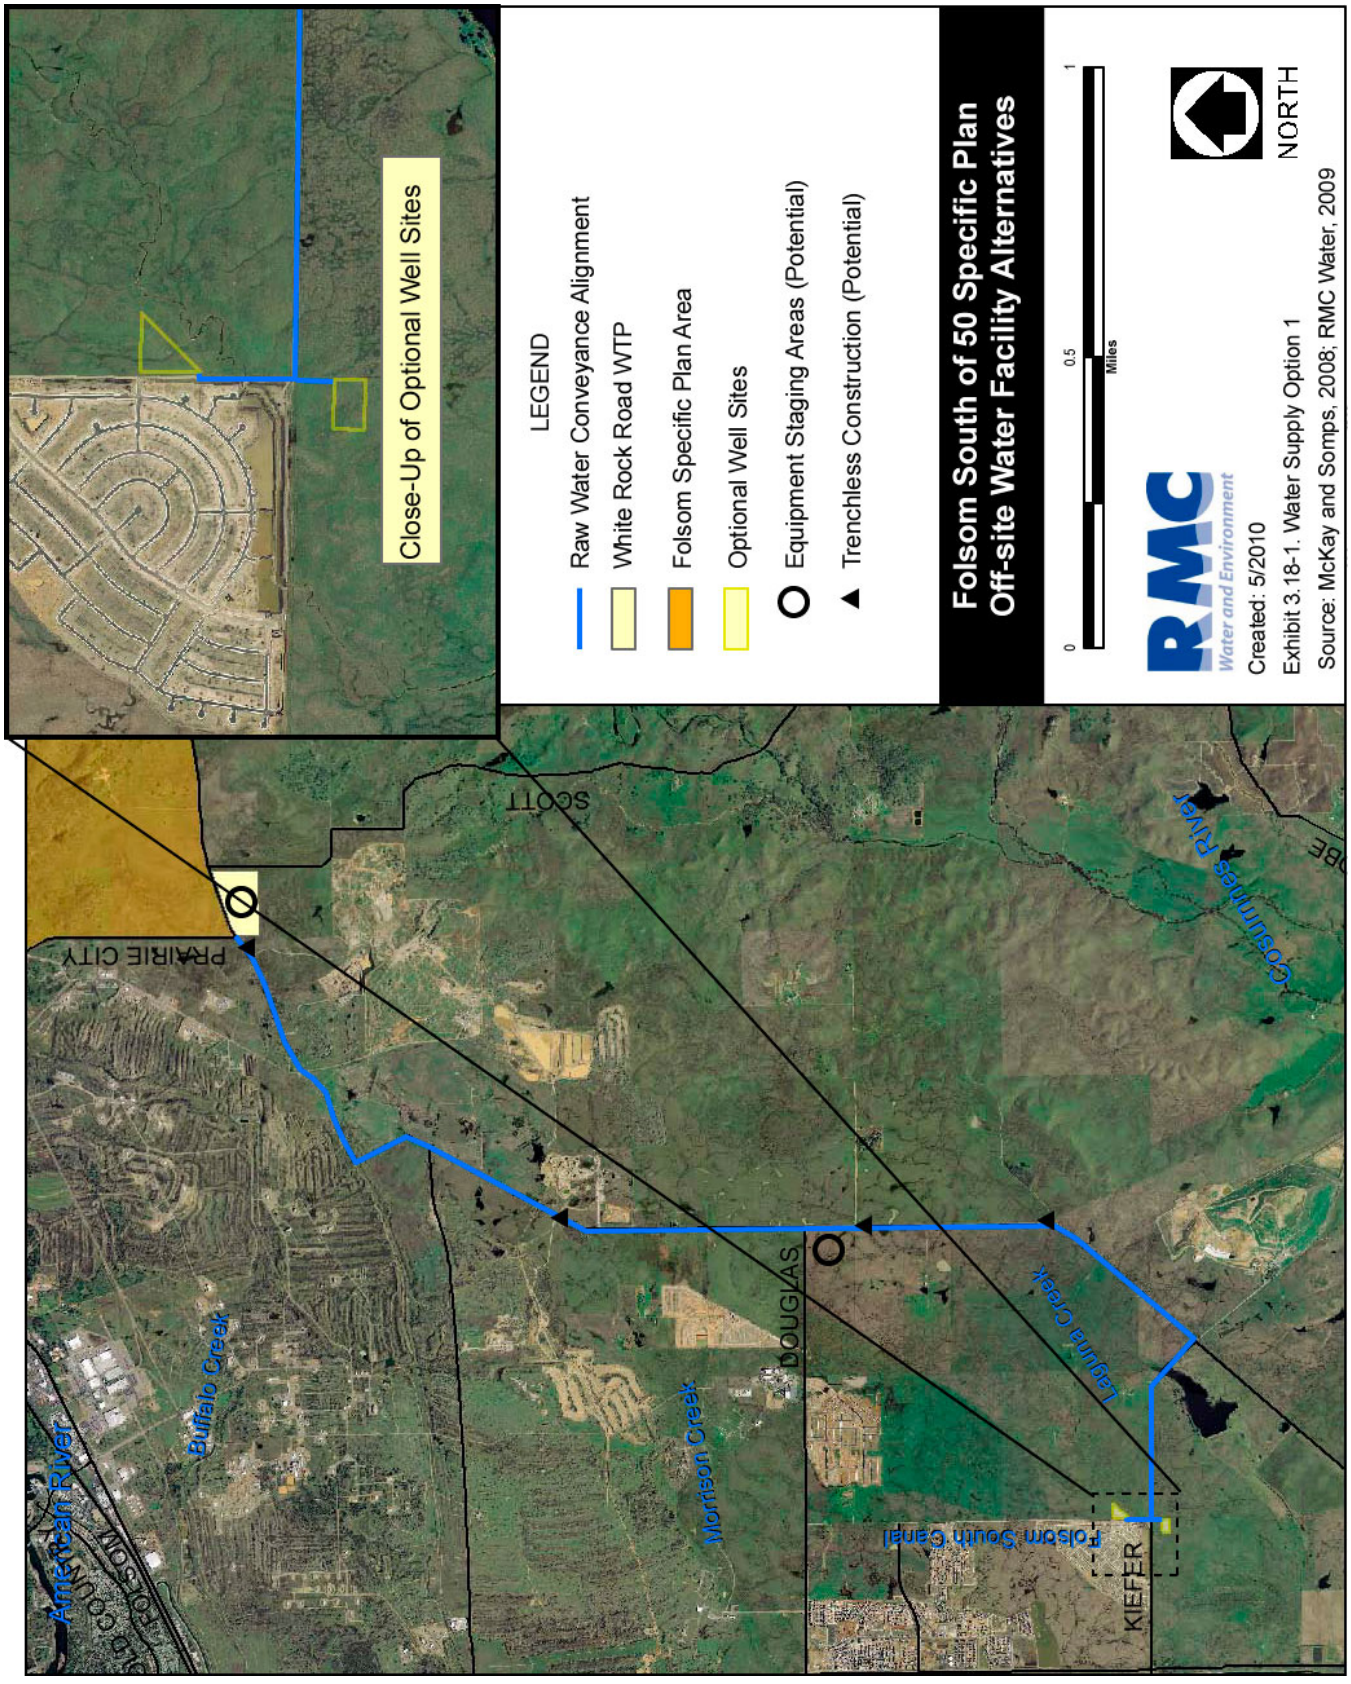
For this water supply option, up to 6.5 mgd of groundwater on average would be pumped from up to two well sites located near the intersection of Kiefer Boulevard and Jaeger Road and within the Suncreek Specific Plan area (see Exhibit 3A.18-1). The City would construct multiple 1,000-gallon-per-minute (gpm) capacity wells at one or both of the optional well sites. The two well sites are currently proposed for Public/Quasi-Public uses within the Suncreek Specific Plan area. The well field sites would be contained within an area totaling up to one acre. For the purposes of analysis, the City assumes that the wells could be drilled to depths of up to 500 feet below the ground surface (bgs). However, the actual depth of the wells has yet to be determined.

A new 30-inch, raw-water transmission pipeline would be constructed to convey the pumped groundwater approximately 9 miles from the well sites to the White Rock WTP located immediately south of the Folsom SPA. As shown in Exhibit 3A.18-1, the raw water conveyance pipeline would travel east along Kiefer Boulevard to Grant Line Road where it would then travel to the north to White Rock Road and then back to the east before arriving at the White Rock WTP. Similar to the Off-site Water Facility Alternatives, the conveyance alignment would be placed within roadway rights-of-way (ROW) for its entire length. A treated-water pipeline would extend from the White Rock WTP into the Folsom SPA.

For the purposes of this water supply option and given the complexities associated with operating a conjunctive use program, the City has not assumed the inclusion of any conjunctive use facilities, such as surface water infrastructure. Although the City would attempt to establish a conjunctive use strategy with one or more other groundwater users in the basin, as previously indicated, this water supply option would not explicitly depend on conjunctive use.

Water Supply Certainty

The water supply demand for the Folsom SPA under the Proposed Project is estimated at up to 5,600 AFY and would be well within the safe yield range of the basin. The CSCGMP indicates a 2030 normal year groundwater demand of 235,060 acre-feet, and a dry-year groundwater demand of 261,784. Based on these estimates, there is sufficient groundwater yield capacity for the City to supply the entire Folsom SPA demand using groundwater as the source of potable water supply. For these reasons, this supply is considered to have a high level of certainty.



Water Supply Option 1: Groundwater from the Central Sacramento Groundwater BasinExhibit 3A.18-1

Impact Discussion

Aesthetics

The description of the affected environment for Zone 4 of the "Water" Study Area as provided in Section 3B.1, "Aesthetics – Water," would apply for this water supply option With implementation of mitigation recommended in Section 3B.1, potentially significant impacts related to exterior finishes and nighttime security lighting would be **similar** and minimized through mitigation identified in Section 3B.1, "Aesthetics – Water," to **less-than-significant** levels.

Air Quality and Climate Change

Water Supply Option 1 lies within the same air quality setting as that described for the Off-site Water Facility Alternatives in Section 3B.2, "Air Quality. - Water." Each of the discussed air quality plans and policies, attainment status and existing air quality conditions for the Off-site Water Facility Alternatives will also apply to Water Supply Option 1. This option would also be located within the jurisdiction of the SMAQMD and will be subject to the SMAQMD's Rules and Regulations.

Sensitive receptors in the vicinity include planned rural and low-density residential land uses associated with the suncreek development located to the northwest of the optional well field site. Construction impacts would be similar in nature and magnitude to those estimated for Off-site Water Facility Alternative 1A. Due to the presence of sensitive receptors in close proximity to the well site(s) and conveyance alignment, construction impacts could be potentially significant. Further, these emissions in conjunction with the construction emissions resulting from installation of the WTP could contribute to exceedances of SMAQMD's standard for NO_X. As a result, this water supply option could result in **similar**, but likely greater, construction impacts as Off-site Water Facility Alternative 1A. These impacts would be **significant and unavoidable** after implementation of Mitigation Measures listed in Section 3B.2, "Air Quality – Water."

Biological Resources

The conveyance facilities for this water supply option follow a similar alignment to that of Proposed Off-site Water Facility Alternative following its crossing of the Folsom South Canal (FSC). Habitats and potentially occurring special status species identified for Proposed Off-site Water Facility Alternative could also be expected to occur in close proximity to the conveyance alignment for this water supply option. The one major exception is that this water supply option would avoid the wetland mitigation areas established west of the FSC and along the existing Freeport Project alignment, east of Eagles Nest Road.

The well fields would be constructed near the headwaters of Laguna Creek, which meanders approximately 100 to 150 yards southeast of the two possible well sites. Several seasonal tributary channels meander through each well site, thereby carrying the potential for direct impacts to wetlands and, potentially, vernal pools. Consequently, this water supply option could also have potential direct impacts on wetland and vernal pool-associated plant and animal species. Because of the proximity of the well sites from the channel, this water supply option is unlikely to result in direct biological impacts to Laguna Creek, but could result in indirect water quality impacts to the creek or adjacent wetland areas. These impacts would be **similar** to the Proposed Off-site Water Facility Alternative and would be **potentially significant**. Mitigation similar to that required for the Proposed Off-site Water Facility Alternative in Section 3B.3, "Biological Resources – Water," would be required under this alternative.

The construction of the well fields and WTP under this water supply option would result in the loss of introduced annual grassland habitat. This would not constitute a significant impact to biological resources due to this habitat type's relative abundance locally and regionally along with the degraded nature (i.e., prevalence of non-native plant species) of much of this community as a result of past land uses. This would be a **less-than-significant** impact.

Swainson's hawk and vernal pool fairy shrimp are documented within the vicinity of the well sites, WTP, and conveyance alignment and may be adversely impacted by the construction of this water supply option through the removal of suitable foraging habitat. Likewise, construction activities associated with this water supply option have the potential to cause nesting burrowing owls, bats, and other raptor species to abandon their nests. Additionally, construction on the WTP site may eliminate potential nest sites for burrowing owls. These would be considered **potentially significant** impacts and **similar** to the Proposed Off-site Water Facility Alternative. Implementation of the mitigation outlined in Section 3B.3, "Biological Resources – Water" would reduce these impact to a less-than-significant level.

Implementation of this water supply option could also result in direct impacts to vernal pool habitats through incidental fill during construction. A loss or "take" of vernal pool-associated species (vernal pool fairy shrimp, vernal pool tadpole shrimp, California linderiella, Boggs lake hedge-hyssop, slender orcutt grass, Sacramento orcutt grass, Crampton's tucktoria, Dwarf downingia, Ahart's dwarf juncus, and legenere) could also occur in this event. This impact is considered **potentially significant** and would require mitigation contained Section 3B.3, "Biological Resources – Water," **similar** to Proposed Off-site Water Facility Alternative.

Lastly, similar to Proposed Off-site Water Facility Alternative, the implementation of this water supply option could result in damage to or removal of native trees during construction activities along the conveyance alignment. This would conflict with policies of the Sacramento County General Plan and Tree Protection Ordinance and would be a potentially significant impact.

Climate Change

Sources of operational emissions associated with this water supply option would be similar to the Proposed Off-site Water Facility Alternative. As a consequence, the operational analysis under this water supply option would likely be similar to those identified for Proposed Off-site Water Facility Alternative in Section 3B.4, "Climate Change - Water." However, with the additional well pumping facilities included under this water supply option, the operational emissions of GHGs would likely be higher than those associated with the Proposed Off-site Water Facility Alternative. In this context, based on the significance determination for Off-site Water Facility Alternative 1A, the contributions of GHGs to regional and global emissions would be **significant and unavoidable** even after implementation of Mitigation Measures listed in Section 3B.4, "Climate Change-Water," **similar** to the Proposed Off-site Water Facility Alternative.

Cultural Resources

The cultural resource setting for water supply option 1 is similar to that of the Proposed Off-site Water Facility Alternative, which is indicative of the Sacramento Valley; a relatively flat plain with meandering rivers and creeks interspersed throughout the landscape. Throughout the prehistoric period, the Sacramento Valley would have provided a rich array of terrestrial and riverine resources for indigenous groups, namely along the nearby riverine environments of Laguna Creek and the Cosumnes River (see Section 3B.5, "Cultural Resources – Water"). However, the principal settlements were located on natural rises set above the periodic flooding of the Delta and the tributaries of the Sacramento and San Joaquin rivers, such as the American and the Cosumnes Rivers.

Artifacts or unusual amounts or types of stone, bone, or shell may be uncovered during site reconnaissance or actual construction activities **similar** to the Proposed Off-site Water Facility Alternative. This would be a **potentially significant** impact that would require mitigation similar to that described in Section 3B.5, "Cultural Resources – Water."

Environmental Justice

No low-income or minority pollutions are identified along the conveyance alignment or WTP for this water supply option and therefore **no impacts** would occur; **similar** to the Proposed Off-site Water Facility Alternative.

Geology, Soils, and Paleontological Resources

This water supply option is mapped on the same geologic formations as of that of the Off-site Water Facility Alternatives. The well sites and conveyance alignment are not mapped within an Alquist-Priolo Earthquake Fault Zone or located within 15 km of a Class A or Class B fault source (DMG Special Publication 42, 1997). Based on these factors, ground rupture at the possible well sites resulting from seismic activity is unlikely. Likewise, the corresponding potential for ground lurching, differential settlement, and/or lateral spreading to occur during or following seismic events near the possible well sites is considered very low and **similar** to the Proposed Off-site Water Facility Alternative. Provided geotechnical engineering recommendations are followed during site preparation as required by mitigation contained in Section 3B.7, "Geology, Soils, and Paleontological Resources - Water," these **potentially significant** impacts would be reduced to a less than significant level.

According to the Soil Survey for Sacramento County (Web Soil Survey 2010), soils located on the possible well and WTP sites may contain expansive clays within some portion of the profile. These soil-related impacts could be **potentially significant** and would be **similar** to the Proposed Off-site Water Facility Alternative thereby requiring mitigation.

This conveyance alignment under this water supply option would be required to cross some of the potentially sensitive paleontological **similar** to the Proposed Off-site Water Facility Alternative. With the implementation of the mitigation measures identified in Section 3B.7, "Geology, Soils, and Paleontological Resources - Water," **potentially significant** impacts related to geology, soils, and paleontological resources would be reduced to a less-than-significant level.

Hazards and Hazardous Materials

The setting description provided for Zone 4 and the White Rock WTP in Section 3B.8, "Hazards and Hazardous Materials-Water," would generally apply to the conveyance and treatment facilities required for this water supply option. The regulatory agency database search complied for the Off-site Water Facility Alternatives included the possible well sites and WTP and revealed no indication of preexisting hazardous materials, LUST, or UST sites on record. The potential to encounter previously undocumented hazardous materials contamination would be **similar** to the Proposed Off-site Water Facility Alternative and **potentially significant**. This impact could be mitigated through the implementation of mitigation in Section 3B.8, "Hazards and Hazardous Materials-Water."

Impacts related to wildlife hazards, risk of upset, and airport safety would be **similar** to the Off-site Water Facility Alternatives and **potentially significant**. This impact could be mitigated through the implementation of mitigation in Section 3B.8, "Hazards and Hazardous Materials-Water."

As described in more detail in Section 3B.17, "Groundwater - Water," several groundwater contaminant plumes exist within the "Water" Study Area and to the north and west of the optional well sites. These plumes are known to exist from source areas at Mather Field, Aerojet, and Boeing and are illustrated in Exhibit 3B.17-3. Although other localized plumes exist in and around Zone 4 of the "Water" Study Area, the principal plumes shown in Exhibit 3B.17-3 are the largest and have the greatest current impact on existing groundwater use. As described in Section 3B.17, "Groundwater - Water," for the Mather Field plumes, the primary contaminants of concern (COCs) are tetrachloroethylene (TCE), perchloroethylene (PCE), and carbon tetrachloride. The Mather Field plume edges represent a composite COC concentration of 0.5 mg/L, which is one-tenth of the maximum contaminant level (MCL) for these constituents. For the Aerojet and Boeing plume, the primary COCs are TCE, n-nitrosodimethylamine (NDMA), and perchlorate.

As part of this water supply option, groundwater resources in the vicinity of Kiefer Road, east of Sunrise Boulevard would be pumped via multiple 1,000 gpm wells with a rated capacity of up to 10 mgd. Under this water supply option, wells would be drilled to depths of up to 500 feet, similar to municipal wells operated by SCWA within eastern portions of SCWA's Zone 40. Table 3A.18-14 shows the water quality for groundwater wells to the north (SCWA – Mather, Anatolia) and south (Laguna, Grant Line) of the two possible well sites. As

provided in Table 3A.18-14, groundwater within the vicinity of these wells meets drinking water standards, but differs substantially between the north and south in certain instances. With an untested level of pumping at the well sites considered for this water supply option, the potential for pumping to result in the migration of these contaminant plumes in the direction optional well or other existing well sites is considered a **potentially significant** impact. This impact is **greater** than groundwater quality impacts associated with the Proposed Off-site Water Facility Alternative. Mitigation for this impact would require the use of sophisticated modeling to enable for prediction of pollutant fate and transport.

For example, wells within the Laguna area to the south of Zone 4 of the "Water" Study Area exhibit elevated levels of nitrates, arsenic, TDS, boron, chromium VI, and THMs (total). In contrast, SCWA's Mather wells to the north exhibit elevated concentrations of lead, high pH, and require mandatory sampling and monitoring for NDMA, TCE, and perchlorate. However, as provided in Table 3A.18-14, these chemical by-products were not detected in 2007 groundwater samples. Based on these results and the fact that local groundwater supplies are already used for potable uses within Zone 4 of the "Water" Study Area, the use of groundwater would not create a significant hazard to users within the Folsom SPA. In contrast to the CVP water supply from NCMWC for the Off-site Water Facility Alternatives, groundwater supplies may exhibit more issues related to taste and odor along with higher TDS levels, which would be considered a **potentially significant** impact; **greater** than the Proposed Off-site Water Facility Alternative.

Hydrology, Water Quality, and Groundwater

The siting of well sites within the Suncreek Specific Plan area would follow the requirements of CDPH Bulletin 79, which requires minimum separation of 50 feet between a sewer line and domestic well. As part of this water supply option's design, the location of all existing utilities, including sewer lines, and registered septic systems within 75 feet of the proposed wells site and pipeline alignments would be determined. If any well is determined to be within the 50 foot separation, the relocation of the pipeline or well, depending on feasibility, will be required to achieve the minimum 50 foot separation. Compliance with these regulations would ensure that impacts to local water supply wells are **less-than significant**. These well-related impacts would be **greater** than the Proposed Off-site Water Facility Alternative.

Groundwater Quality. Activities associated with the construction and operation of the well facilities under this option would involve the pumping of groundwater resources from the north-eastern portion of the South American Subbasin from depths up to 500 feet bgs. Property owned by Aerojet is located approximately four miles north of the well sites and is included on the U.S. EPA's National Priority List (NPL) for contamination that resulted from the manufacturing of liquid and solid propellant rocket fuels. The use of groundwater supplies from this portion of the South American Subbasin has the potential to influence the distribution and extent of existing contamination associated with the Aerojet property to the north-northwest. The main COCs include TCE, NDMA, and perchlorate. The extent of these plumes is illustrated in Figure 3B.17-3.

Portions of the Aerojet property included within the NPL designation were divided into smaller project areas, called Operable Units (OUs), to prioritize investigation and cleanup work (EPA 2007). Two OUs, the Western Groundwater (OU3) and Perimeter Groundwater (OU5), were designated to identify areas where control mechanisms are being implemented to slow the movement of chemicals in groundwater migrating at or beyond the periphery of the Aerojet property. The Western Groundwater OU was the first such area to be investigated with cleanup actions currently being implemented (EPA, 2007). These actions include containing, treating, and discharging the contaminated groundwater on the western and northwestern sides of the property through Aerojet's GET program to prevent the continued migration of chemicals off-site in groundwater. The treatment strategy involves removal of perchlorate, nitrate, and nitrite using a biological treatment process developed by Aerojet; removal of NDMA and high level VOCs with ultraviolet light; and removal of the remaining VOCs by air stripping or carbon filtration. A total of 33 extraction wells are currently in operation, and another four wells were planned for operation by the end of 2007 (Sacramento County, 2008b).

Table 3A.18-14
Treated Groundwater Quality Data for SCWA's Eastern Service Areas

Parameter	Units	Municipal Drinking Water Standards				Treated SCWA Groundwater (2007)	
		MCL	SMCL	PHG (MCLG)	DLR	Mather, Sunrise, Anatolia - Range (Min/Max)	Laguna, Vineyard, Grant Line - Range (Min/Max)

The Perimeter Groundwater OU encompasses four additional groundwater zones along the northern, eastern, and southern boundaries of the Aerojet property. The final Perimeter Groundwater OU Remedial Investigation/Feasibility Study (RI/FS) was anticipated in 2008, but was not available for review prior to circulation of this EIR/EIS. The RI/FS will include a determination of the appropriate remedial action for the investigated areas. Given that the groundwater plume is not fully contained or remediated and may be susceptible to movement by operations of nearby wells, it is not known whether the operation of the wells under this option could contribute to effects or alter the distribution of this contaminant zone. With an untested level of pumping at the well sites considered for this water supply option, the potential for pumping to result in the migration of these contaminants in the direction well sites is considered a **potentially significant** impact that is **greater** than groundwater quality impacts associated with the Proposed Off-site Water Facility Alternative. Mitigation for this impact would require the use of sophisticated modeling to enable for prediction of pollutant fate and transport.

Kiefer Landfill is located to the south east of the well sites. A release of waste constituents from the landfill to groundwater was discovered in 1989. Since then, numerous detection and corrective action monitoring wells have been installed. Monitoring of the shallow Zone[1] A shows the presence of various VOCs, including, but not limited to, tetrachloroethene, trichloroethene, 1,2-dichloroethene, and vinyl chloride. The shallow VOC plume extends beyond the landfill footprint about 4,000 feet to the southwest. The source area was identified as the unlined landfill Module M1. No VOCs have been detected in the lower aquifer since 1999 when trace levels were still present.

In 1995, Sacramento County installed a groundwater extraction system, including several extraction wells and a pump and treat system. Groundwater is currently extracted from 14 wells at a combined average rate of about 1,000 gpm. The system includes two air stripper towers, a carbon absorption filter, and several extraction wells. Pump and treat remediation began in April 1995, with the objective of containing the spread of the plume and reducing VOC levels in the source area. According to the monitoring reports submitted through 2006, groundwater extraction has removed over 700 pounds of VOCs from the groundwater since 1995, and resulted in an approximate 75% reduction in mass of VOCs in the groundwater (RWQCB, Order No. R5-2007-0014, 2007).

Due to the preexisting sources of nearby contamination, this option could cause potentially significant impacts in the form of increased migration of the existing contaminated groundwater plumes. Mitigation would be required as an assurance that new pumping as part of the operation of the well facilities does not affect the migration of existing contaminants. However, even with this mitigation, the City would be unable to guarantee that this potential impact could be reduced to a less-than-significant level until pumping has commenced over time. For this reason, this impact is considered **significant** and **unavoidable** and **greater** than the Proposed Off-site Water Facility Alternative.

*Groundwater Withdrawal***.** The operation of the wells under this option would require the direct pumping of groundwater at a maximum rate of up to 5,600 AFY. As indicated in the setting discussion in Section 3B.17, "Groundwater - Water," the WFA sets the sustainable yield for the South American Subbasin at 273,000 AFY. Based on information contained in the Freeport Project EIR (2003) and CSCGMP (2006), current groundwater demands (2005) within the South American Subbasin are estimated at 250,000 AFY. Of this total, SCWA currently pumps, on average, 131,000 AFY. With the completion of the Freeport Project, SCWA anticipates diverting up to 90,000 AFY[2] of surface water during normal years thereby reducing its groundwater pumping to 41,000 AFY. This initial reduction in groundwater demand from SCWA would reduce total groundwater demand within the South American Subbasin to 159,000 AFY. Given that the Freeport Project would be online in advance of this option's operation, total groundwater demands under a worst-case, critical dry year scenario would only be increased to 164,500 AFY. Given that this estimate is substantially lower than the South American Subbasin's sustainable yield of 273,000 AFY, the additional demands for groundwater under this option would have **less-**

[1] A-zone lies between approximately 60 and -20 feet mean sea level (MSL), with groundwater first encountered at about 60 to 190 feet below the ground surface.

[2] SCWA's total surface water supplies for Zone 40 are assumed to include 68,500 AFA in CVP and appropriated supplies and 12,000 AFA and 9,300 AFA from the Purveyor Specific Agreement with the City of Sacramento.

than-significant impacts and would not be expected to lead to overdraft of groundwater basin. This impact; however, would be **greater** than the Proposed Off-site Water Facility Alternative.

Over the long-term, total water demands within the South American Subbasin are estimated to approach approximately 255,000 AFY[3,4] in the year 2030 for a critically dry year (CSCGMP, 2006). Total groundwater demand becomes substantially reduced at 235,000 AFY during wet and normal years when surface water supplies are available, thereby allowing the basin to recharge. Under this option, total groundwater demands could approach 260,500 AFY[5] by 2030. This estimate is short of the 273,000 AFY sustainable yield estimate for the South American Subbasin based on the WFA and leaves a margin of 12,500 AFY of available capacity for other potential users under future conditions. Because groundwater pumping directly and indirectly associated with this water supply option would not exceed sustainable yield recommendations, groundwater levels within the South American Subbasin under future conditions are projected to remain at levels above those accepted by the WFA. Based on these findings, this impact is considered less than significant.

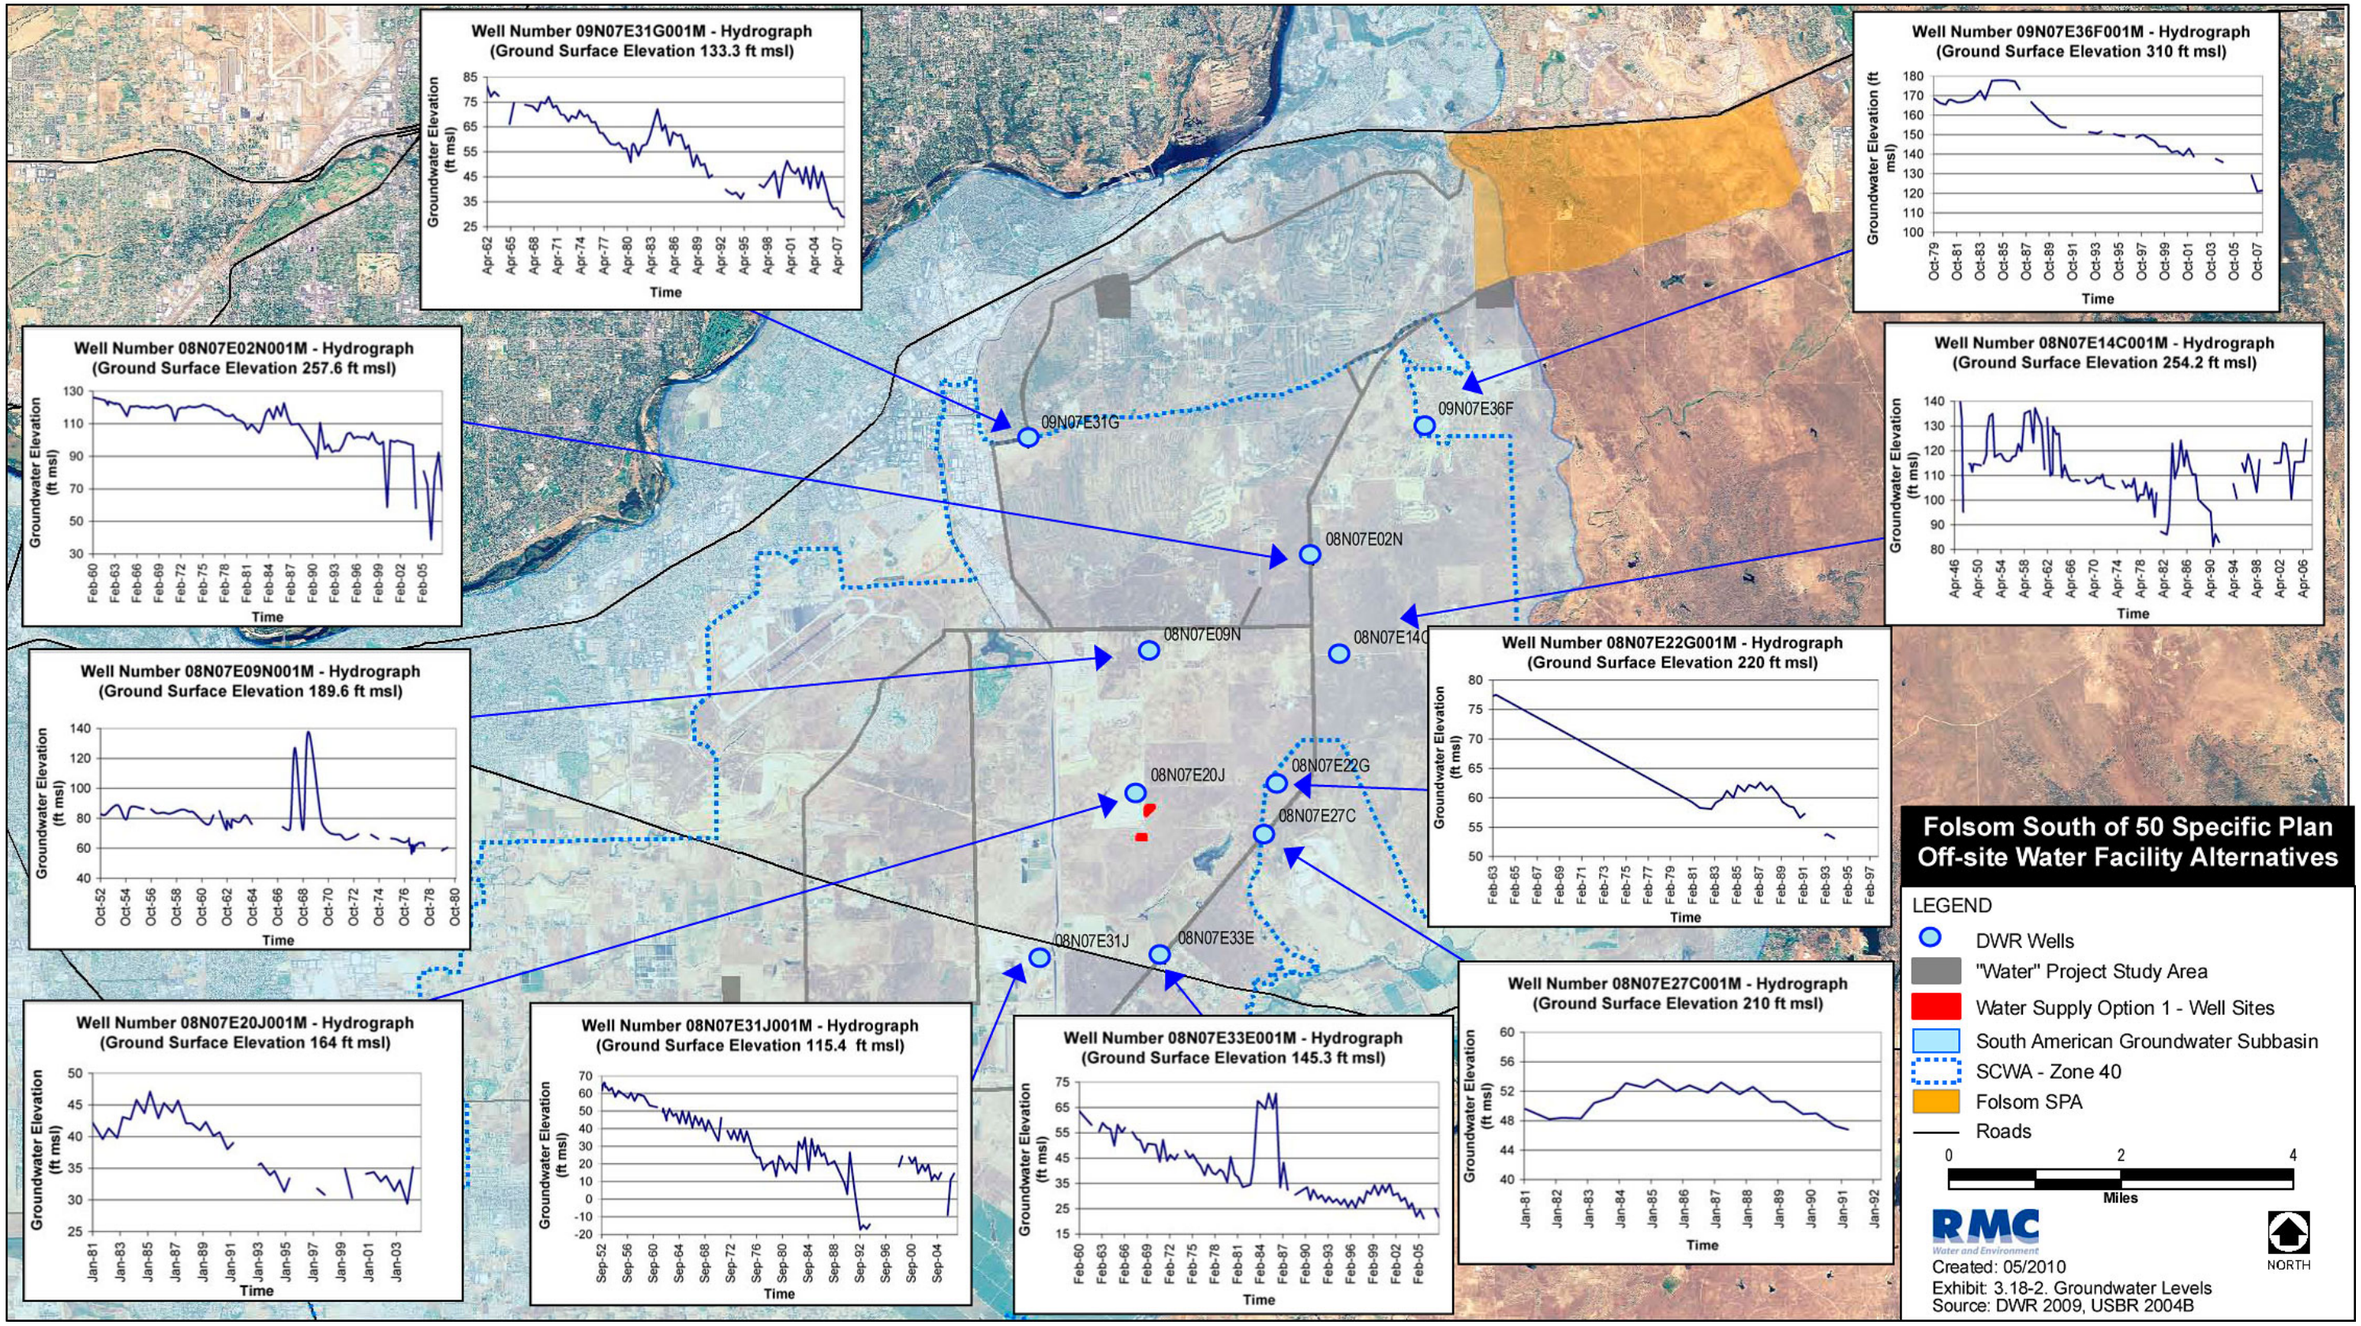
Under cumulative conditions and beyond 2030, other sources of demand are identified in the Sacramento County General Plan Update EIR in unincorporated portions of the County. These additional sources of demand combined with the Folsom SPA could lead to exceedances of the groundwater basin's safe yield and lead to a further lowering of the regional aquifer. This would be a **significant** and **unavoidable**, cumulative impact that is **greater** than groundwater impacts associated with the Proposed Off-site Water Facility Alternative.

Drawdown in Adjacent Wells. From a more localized perspective, the well facilities under this option would include multiple wells that would have individual capacities of 1,000 gpm and drilled to a depth of less than 500 feet bgs. With new pumping comes the potential for localized drawdown to occur and the potential for lowering of groundwater levels in adjacent wells depending on the rate aquifer recovery. Current literature suggests that the deep, water-bearing zones of the Mehrten Formation can yield between 1,000 and 1,400 gallons per minute (gpm) with a specific capacity of 46–100 gpm per foot of drawdown (ERM 2003). These yields are highest in the central portion of the valley, where well-sorted sands are predominant, and lowest along the eastern margins of the Sacramento Valley.

Without actual pump testing, the City is unable to quantify the duration of any drawdown and whether groundwater levels would return to pre-pumping levels following one or more normal to above normal precipitation cycles. In assuming a localized drawdown within a range of 20 to 40 feet and in evaluating the historical data provided in Exhibit 3A.18-2, drawdowns could exceed the historical range of groundwater level fluctuations during drought conditions. Groundwater pumped from the wells could affect existing irrigation wells and nearby wells planned by SCWA, potentially reducing pumping performance and resulting in increased energy consumption due to an increase in required pumping lift. The effects of any localized drawdown could result in localized impacts that could be **potentially significant** to adjacent groundwater uses, but less than significant in the context of the larger groundwater basin. These impacts would be **greater** than the Proposed Off-site Water Facility Alternative and would require mitigation in the form of a Well Operations Optimization Plan to determine optimal operating performance criteria to minimize drawdown in adjacent wells.

Alteration of Surface Water Hydrology. As part of this option, the City would rely on groundwater extracted from multiple groundwater wells to meet water demands for the Folsom SPA. The groundwater would be extracted from wells constructed to a depth of 500 feet and tap water-bearing sediments within the Mehrten Formation. No drilling investigations have been conducted at the possible well sites under evaluation and, therefore, the site-specific composition of the underlying geologic materials is not known.

[3] A conservation factor or 25.6 percent is applied to 2030 water demand estimates per the WFA.
[4] Groundwater use for 2030 assumes the inclusion of Aerojet GET extraction rates, estimated at 35,890 AFY.
[5] Estimate based on an average annual increase in pumping within SCWA's service are of 6.4 mgd or 7,200 AFY.



Groundwater Hydrographs for the Eastern South American Subbasin **Exhibit 3A.18-2**

The interaction between groundwater and surface water has not been extensively evaluated in the South American Basin. A recent draft decision by the SWRCB (2003) regarding the American River concluded that from Nimbus Dam to about 6,000 feet below the dam, groundwater elevations and surface water elevations were similar enough to each other that groundwater could be tributary to the American River. Beyond 6,000 feet down river from the dam, groundwater elevations are sufficiently lower than the river channel to conclude that the American River is a "losing" stream down to its confluence with the Sacramento River.

The wells constructed under this option would be at depths that would be expected to provide sufficient separation between the wells and the American River, which is more closely linked to groundwater associated with the Laguna formation. Given that these wells would tap geologic materials substantially lower than the Laguna formation and the well sites are located over five miles south of the River, this option is expected to result in **less-than-significant** impacts to surface water flows within the American River; however, any impacts could be **greater** when compared to the Proposed Off-site Water Facility Alternative.

Surface Hydrology and Water Quality. No impacts related to changes in flows within the Sacramento River would occur under this water supply option. Other impacts related to increases in runoff as a result of new imperious surfaces, and construction-related water quality concerns would be **similar** to the Proposed Off-site Water Facility Alternative. These impacts would be **similar** to the Proposed Off-site Water Facility Alternative and would be **potentially significant**, but reduced to a less-than-significant level through the implementation of mitigation prescribed in Section 3B.9, "Hydrology and Water Quality – Water."

Land Use and Agricultural Resources

Existing land uses surrounding the facilities described for this water supply option would be similar to those described for the Off-site Water Facility Alternatives in Section 3B.10, "Land Use and Agricultural Resources – Water." The optional wells sites are generally vacant and comprise non-native annual grassland. New low-density residential uses are currently planned for much of the surrounding area. Both well sites are located on lands designated as "Public" uses in the Suncreek Specific Plan. The number of residences in the vicinity of the well sites affected by the operation of the pumping facilities and well fields would depend on the location, configuration of the well sites, and the proximity of new residential structures. Potential impacts resulting from this close proximity could involve nuisance-related effects that are minor and considered less-than-significant.

The construction of the well field(s), pump and conveyance facilities, and WTP under water supply Option 1 would not convert any prime farmland, unique farmland, or farmland of statewide importance, as shown on the maps prepared pursuant to the Farmland Mapping and Monitoring Program of the California Resources Agency, to non-agricultural uses. Likewise, this area is currently planned for residential development and all Williamson Act Contracted lands are currently under cancellation or non-renewal status. However, **similar** to the Proposed Off-site Water Facility Alternative, premature cancellation of a Williamson Act Contract is considered a **significant and unavoidable** impact of Water Supply Option 1.

Typically in most areas of California, overlying land owners and groundwater appropriators may extract percolating ground water and put it to beneficial use without approval from the SWRCB. In general, overlying landowners' rights to such ground water are senior to those of appropriators, which are entities that do not use pumped water on property that they own that also overlies the relevant ground water basin. Under this water supply option, the City would be a ground water appropriator. California does not have a permit process for regulation of ground water use. In several basins, however, groundwater use is subject to regulation in accordance with court decrees adjudicating the ground water rights within the basins. There has not been, however, any adjudication of the groundwater basin that is relevant for this water supply option.

Under this water supply option, the City would be effectively appropriating up to 5,600 AFY of groundwater and conveying this water to the Folsom SPA. Sacramento County has an adopted Groundwater Ordinance that addresses the export of groundwater and surface water within the County. The ordinance requires that

groundwater not be transported from the County without a permit issued by the Sacramento County Department of Water Resources. By virtue that the pumped groundwater would remain within the County, the use of groundwater as proposed under this option is not inconsistent with State or county law, but may be subject to priorities from other overlying groundwater users in the future. This impact is considered **less-than-significant**, but **greater** than the Proposed Off-site Water Facility Alternative.

Noise

The ambient noise environment for this water supply option is similar to that described for Off-site Water Facility Alternatives 1 and 1A. Sensitive receptors identified for Off-site Water Facility Alternative 1 would be similar to this option. Likewise, applicable noise regulations and standards for this option are the same as discussed for Off-site Water Facility Alternatives 1 and 1A.

Construction activities would result in temporary increases in noise levels in the vicinity of the conveyance alignment, well, and WTP site. Construction activities would generate noise levels **similar** to the Proposed Off-site Water Facility Alternative corresponding to the appropriate phase of construction and the noise-generating equipment used during those phases. These impacts could be **potentially significant**.

Construction-related noise levels would be comparable in magnitude with those identified for Off-site Water Facility Alternative 1. Construction noise at nearby residential locations would be substantially greater than existing noise levels and would likely increase day-night levels in close proximity to the construction areas during construction. This would be considered a temporary but significant impact. As is the case with Proposed Off-site Water Facility Alternative, **potentially significant** construction noise impacts under this option would be reduced to a less-than-significant level with the incorporation of mitigation measures identified in Section 3B.11, "Noise – Water."

The principal long-term, operational noise impacts resulting from this option would result from the pumps and generators operated at the well site, booster pump station, and the WTP. Impacts resulting from the WTP and booster pump station would be the same as those discussed in Section 3B.11, "Noise – Water." It is expected that noise generated from the well pumps would be similar to that of the other facility pumps. Based on the findings contained in Section 3B.11, "Noise – Water" for these facilities, the combined operation of the pumps and back-up generator, depending on the proximity to the nearest sensitive receptor could result in a **potentially significant** impact; **similar** to the Proposed Off-site Water Facility Alternative. Mitigation measures identified in Section 3B.11, "Noise – Water" would reduce these impacts to a less-than-significant level.

Recreation

This option would be constructed within urbanizing portions of eastern Sacramento County and is not expected to result in substantial deterioration of existing scenic vistas or natural landscapes at the well field or WTP. This water supply option would avoid impacts to the FSC and, therefore, impacts would be **lesser** under this water supply option and **less-than-significant**.

Traffic and Transportation

Similar to Proposed Off-site Water Facility Alternative, a majority of the conveyance pipeline under this option would be constructed within existing roadway rights of way (ROW). Traffic-related impacts associated with this option would generally be associated with construction in the form of short-term and intermittent reductions of roadway capacities associated with the movement of construction equipment. Lane blockage caused by construction traffic would also be temporary and would only affect roadway capacity within the immediate vicinity of pipeline construction. These impacts would be **potentially significant**, but could be reduced to a less-than-significant, **similar** to the Proposed Off-site Water Facility Alternative, with mitigation contained in Section 3B.15, "Traffic and Transportation-Water."

Over the longer-term, this option would generate a negligible operational vehicle trips and, therefore, is not expected to result in long-term degradation in roadway operating conditions or level of service. **Similar** to the Proposed Off-site Water Facility Alternative, this impact would be less-than-significant.

Utilities and Service Systems

This option would be constructed within the same general vicinity as the Off-site Water Facility Alternatives with several municipal and private utilities located in the area, including those owned and operated by SCWA, PG&E, Sacramento Municipal Utility District (SMUD), Sacramento Regional County Sanitation District (SRCSD) and County Sanitation District (CSD)-1a. Construction activities associated with his option could potentially result in a disturbance of existing utilities or conflict with planned utility projects. This impact is considered **potentially significant**, but **similar** to the Proposed Off-site Water Facility Alternative, this impact could be reduced to a less-than significant level through mitigation contained in Section 3B.16, "Utilities and Service Systems – Water."

The solid waste generated by this option along with the energy required during its construction and long-term operation would be similar to that of Proposed Off-site Water Facility Alternative. This Option would require the implementation of mitigation contained in Section 3B.4, "Climate Change - Water," to encourage energy efficiency and minimize this option's carbon footprint. **Similar** to the Proposed Off-site Water Facility Alternative, this impact would be **less-than-significant**.

Water Supply Option 1 Conclusion

Water Supply Option 1, which would use groundwater supplies from the Central Sacramento County Groundwater Basin, entails concerns related to the long-term reliability of groundwater supplies. In addition, there are also concerns related to the migration of existing groundwater contamination in eastern Sacramento County as a result of additional pumping under this water supply option.

Option 2 – Other Senior Sacramento River Water Right Holders

Under Option 2, the City would acquire up to 8,000 AFY from one or more senior water rights holders on the Sacramento River to meet dry-year conditions. Supplemental water supplies could be purchased by the City from one or more of the following potential senior water rights holders: Anderson-Cottonwood Irrigation District, Conaway Preservation Group, Reclamation District 108, and River Garden Farms Company. Water assignment amounts would not exceed 8,000 AFY from any single party.

These willing water sellers would make water available to the City by substituting local groundwater for their existing surface water supplies or by implementing water conservation measures. Similar to the Off-site Water Facility Alternatives, the undiverted surface water would flow downstream to the Freeport Project intake facility where it would be diverted for use by the City. The conveyance facilities required under this water supply option could essentially include any one of the combinations analyzed for each of the Off-site Water Facility Alternatives in the "B", or "Water" sections of Chapter 3.

Water Supply Certainty

The water supplies obtained under Option 2 would likely consist of CVP Water from other willing sellers within the Sacramento River Basin. These supplies would have a similar level of moderate to high certainty to that of the Off-site Water Facility Alternatives.

Aesthetics

The description of the affected environment for Zone 4 of the "Water" Study Area as provided in Section 3B.1, "Aesthetics – Water," would apply for this water supply option. With implementation of mitigation recommended in Section 3B.1, potentially significant impacts related to exterior finishes and nighttime security lighting would be **similar** to the Proposed Off-site Water Facility Alternative and minimized through mitigation identified in Section 3B.1, "Aesthetics – Water," to **less-than-significant** levels.

Air Quality

Air quality impacts resulting from water supply Option 2 would be similar to those identified for the Off-site Water Facility Alternatives in Section 3B.2, "Air Quality – Water." Even with the implementation of mitigation similar to that described for the Off-site Water Facility Alternatives in the "B", or "Water" sections of Chapter 3, air quality impacts during construction would **significant**; **similar** to the Proposed off-site Water Facility Alternative.

Operational impacts resulting from this water supply option would be **less than significant**; **similar** to the Proposed Off-site Water Facility Alternative.

Biological Resources

The conveyance facilities for this water supply option follow a similar alignment to one of the Off-site Water Facility Alternatives described in Chapter 2, "Alternatives". Habitats, wetlands, and potentially occurring special status species identified for the Proposed Off-site Water Facility Alternative could also be expected to occur in close proximity to the conveyance alignment for Water Supply Option 2. Water supply option could also result in direct impacts to vernal pool habitats through incidental fill during construction. A loss or "take" of vernal pool-associated species (vernal pool fairy shrimp, vernal pool tadpole shrimp, California linderiella, Boggs lake hedge-hyssop, slender orcutt grass, Sacramento orcutt grass, Crampton's tucktoria, Dwarf downingia, Ahart's dwarf juncus, and legenere) could also occur in this event. Impacts to riparian corridors, oak trees, and fisheries would be similar to the Proposed Off-site Water Facility Alternative. These impacts are considered **potentially significant** and would require mitigation contained Section 3B.3, "Biological Resources – Water," **similar** to the Proposed Off-site Water Facility Alternative.

Unlike the Proposed Off-site Water Facility Alternative, this water supply option could result in greater withdraw of groundwater from underlying aquifers to supplement the surface water supplies assigned to the City. Increased groundwater pumping could result in corresponding reductions in water levels within nearby surface waterways. Changes in water levels within affected surface water features could result in corresponding changes to vegetation along the banks. This change could modify existing habitat conditions thereby resulting in potential impacts to special status species, including the giant garter snake. This impact is considered **potentially significant** and would be **greater** than those associated with the Proposed Off-site Water Facility Alternative.

Climate Change

Sources of operational emissions associated with this water supply option would be similar to the Proposed Off-site Water Facility Alternative. As a consequence, the operational analysis under this water supply option would likely be similar to those identified for Proposed Off-site Water Facility Alternative in Section 3B.4, "Climate Change - Water." In this context, based on the significance determination for Off-site Water Facility Alternative 1A, the contributions of GHGs to regional and global emissions would be **significant and unavoidable** even after implementation of Mitigation Measures listed in Section 3B.4, "Climate Change-Water," **similar** to the Proposed Off-site Water Facility Alternative.

Cultural Resources

Impacts to cultural resources from water supply Option 2 would be **similar** to those identified for the Off-site Water Facility Alternatives and would require mitigation similar to that provided in Section 3B.5, "Cultural Resources - Water." With implementation of mitigation similar to that described for the Off-site Water Facility Alternatives in the Section 3B.5, "Cultural Resources – Water," **potentially significant** impacts to historical and archaeological resources would be reduced to a less-than-significant level.

Environmental Justice

No low-income or minority pollutions are identified along the conveyance alignment or WTP for this water supply option and therefore **no impacts** would occur; **similar** to the Proposed Off-site Water Facility Alternative.

Geology, Soils, and Paleontological Resources

Issues related to soils and geology under water supply Option 2 would similar to those identified for the Off-site Water Facility Alternatives in Section 3B.7, "Geology, Soils, and Paleontological Resources." Similar to the Off-site Water Facility Alternatives, this water supply option would not interfere with the availability of any locally or regionally mapped mineral resource area, but could be impacted by localized soil and geologic conditions. Additionally, the conveyance alignment under this option could encounter paleontological impacts at its eastern extent. With mitigation **similar** to that described for the Off-site Water Facility Alternatives in the "B", or "Water" sections of Chapter 3, **potentially significant** soils, geology, and paleontological impacts would be reduced to a less-than-significant level.

Hazards and Hazardous Materials

Public health and safety impacts resulting from water supply Option 2 would be similar to those identified for the Off-site Water Facility Alternatives in Section 3B.8, "Hazards and Hazardous Materials." With mitigation similar to that described for the Off-site Water Facility Alternatives in the "B", or "Water" sections of Chapter 3, **potentially significant** impacts to public health and safety would be reduced to a less-than-significant level.

As previously indicated for the Off-site Water Facility Alternatives, the water quality within the Sacramento River meets all standards for drinking water and, therefore, this source water supply is acceptable for consumptive use and the impact would be **less-than-significant**; similar to the Proposed Off-site Water Facility Alternative.

Hydrology, Water Quality, and Groundwater

Under water supply Option 2, surface water assigned from senior water rights holders to the City would more than likely be replaced by groundwater pumping in their respective service areas. Groundwater pumped as a result of new pumping operations could contain higher levels of salts, dissolved solids, and other constituents when compared to surface water presently used in their service areas. The substitution and use of groundwater for agricultural purposes could alter the quality of agricultural runoff or drainage.

However, substitution of groundwater for surface water in these areas is not expected to result in increased levels of boron and TDS in water applied to agricultural fields, because groundwater would be diluted with surface water. Therefore, it is not anticipated that these increased levels would substantially degrade groundwater quality or result in the exceedance of any water quality standard or discharge requirement. Therefore, the impact would be **less than significant**. This impact could be **greater** than the Proposed Off-site Water Facility Alternative as not groundwater substitution would be required.

Implementation of a water assignment and replacing surface water supplies with increased groundwater pumping within upstream senior water rights holders' service areas could result in potential groundwater drawdowns during drier water years and multiple-year drought conditions. This would be a **potentially significant** and

unavoidable impact of this water supply option that would require mitigation to minimize impacts of drawdown in adjacent wells. This impact could be **greater** than the Proposed Off-site Water Facility Alternative.

Similar to the Proposed Off-site Water Facility Alternative, impacts related to changes in flows within the Sacramento River would be expected to be **less-than-significant**. Other impacts related to increases in runoff as a result of new imperious surfaces, and construction-related water quality concerns would be **similar** to the Proposed Off-site Water Facility Alternative. These impacts would be **similar** to the Proposed Off-site Water Facility Alternative and would be **potentially significant**, but reduced to a less-than-significant level through the implementation of mitigation prescribed in Section 3B.9, "Hydrology and Water Quality – Water."

Land Use and Agricultural Resources

Land use conflicts resulting from water supply Option 2 would be similar to those identified for the Off-site Water Facility Alternatives in Section 3B.10, "Land Use and Agricultural Resources - Water." With implementation of mitigation similar to that described for the "B", or "Water" sections of Chapter 3, land use conflicts during construction, disruption of access, and other nuisance-type effects would be minimized to a **less-than-significant** level; similar to the Proposed Off-site Water Facility Alternative.

The assignment of surface water entitlements from the senior Sacramento River water-right holders for use within the Folsom SPA would generally be consistent with the Water Forum Agreement, the State Water Plan, and the City's General Plan. This would be a **less-than-significant** impact; similar to the Proposed Off-site Water Facility Alternative

Noise

Construction and operational noise impacts resulting from water supply Option 2 would be similar to those identified for Off-site Water Facility Alternatives in Section 3B.11, "Noise - Water." With the implementation of mitigation similar to that described for the Off-site Water Facility Alternatives in the "B", or "Water" sections of Chapter 3, noise impacts from construction and operation of this water supply option would be reduced to a **less-than-significant** level.

Recreation

Under Option 2, impacts to recreational resources would be **similar** to that of the Proposed Off-site Water Facility Alternative. With the implementation of mitigation from Section 3B.12, "Parks and Recreation – Water," **potentially significant** impacts to access along the FSC would be minimized to a less-than-significant level.

Traffic and Transportation

Impacts to traffic and alternative forms of transportation under water supply Option 2 would be **lesser** than those identified for the Off-site Water Facility Alternatives in Section 3B.15, "Traffic and Transportation - Water." The primary reason for this reduction in the level of impact is attributed to the location of the planned facilities under this water supply option, which coincide with planned roadway facilities that have yet to be constructed. Mitigation similar to that described for the Off-site Water Facility Alternatives in the "B", or "Water" sections of Chapter 3 would still be required to minimize impacts to traffic circulation along Prairie City Road to a **less-than-significant** level.

Utilities and Service Systems

Impacts to public services and utilities under water supply Option 2 would be **similar** to those identified for the Proposed Off-site Water Facility Alternative in Section 3B.16, "Utilities and Service Systems - Water." With implementation of mitigation similar to that described in Section 3.16, "Utilities and Service Systems – Water," **potentially significant** impacts to public services and utilities would be reduced to a less-than-significant level.

Option 2 Conclusion

If the City were to acquire water supplies from one or more CVP settlement contractors, the impacts would be very similar to the off-site water Facility Alternatives because the City operations and facilities would be very similar. One impact that might be greater with this option would be impacts to groundwater in the transferor's area. Because a transferor might replace the supply it transferred with groundwater pumping.

Water Supply Option 3 – Conservation of Existing Entitlements and Water System Retrofit

Currently, the City implements a variety of water conservation practices. These are consistent with the best management practices (BMPs) identified in the California Urban Water Conservation Council's (CUWCC) Memorandum of Understanding and include, but are not limited to, tiered pricing, water meters, leak audits, and public education. These programs are still in the process of being fully implemented (e.g. water metering, etc.). The City's Water Management Program offers numerous programs directed towards conserving water uses for commercial, residential, and landscaping purposes.

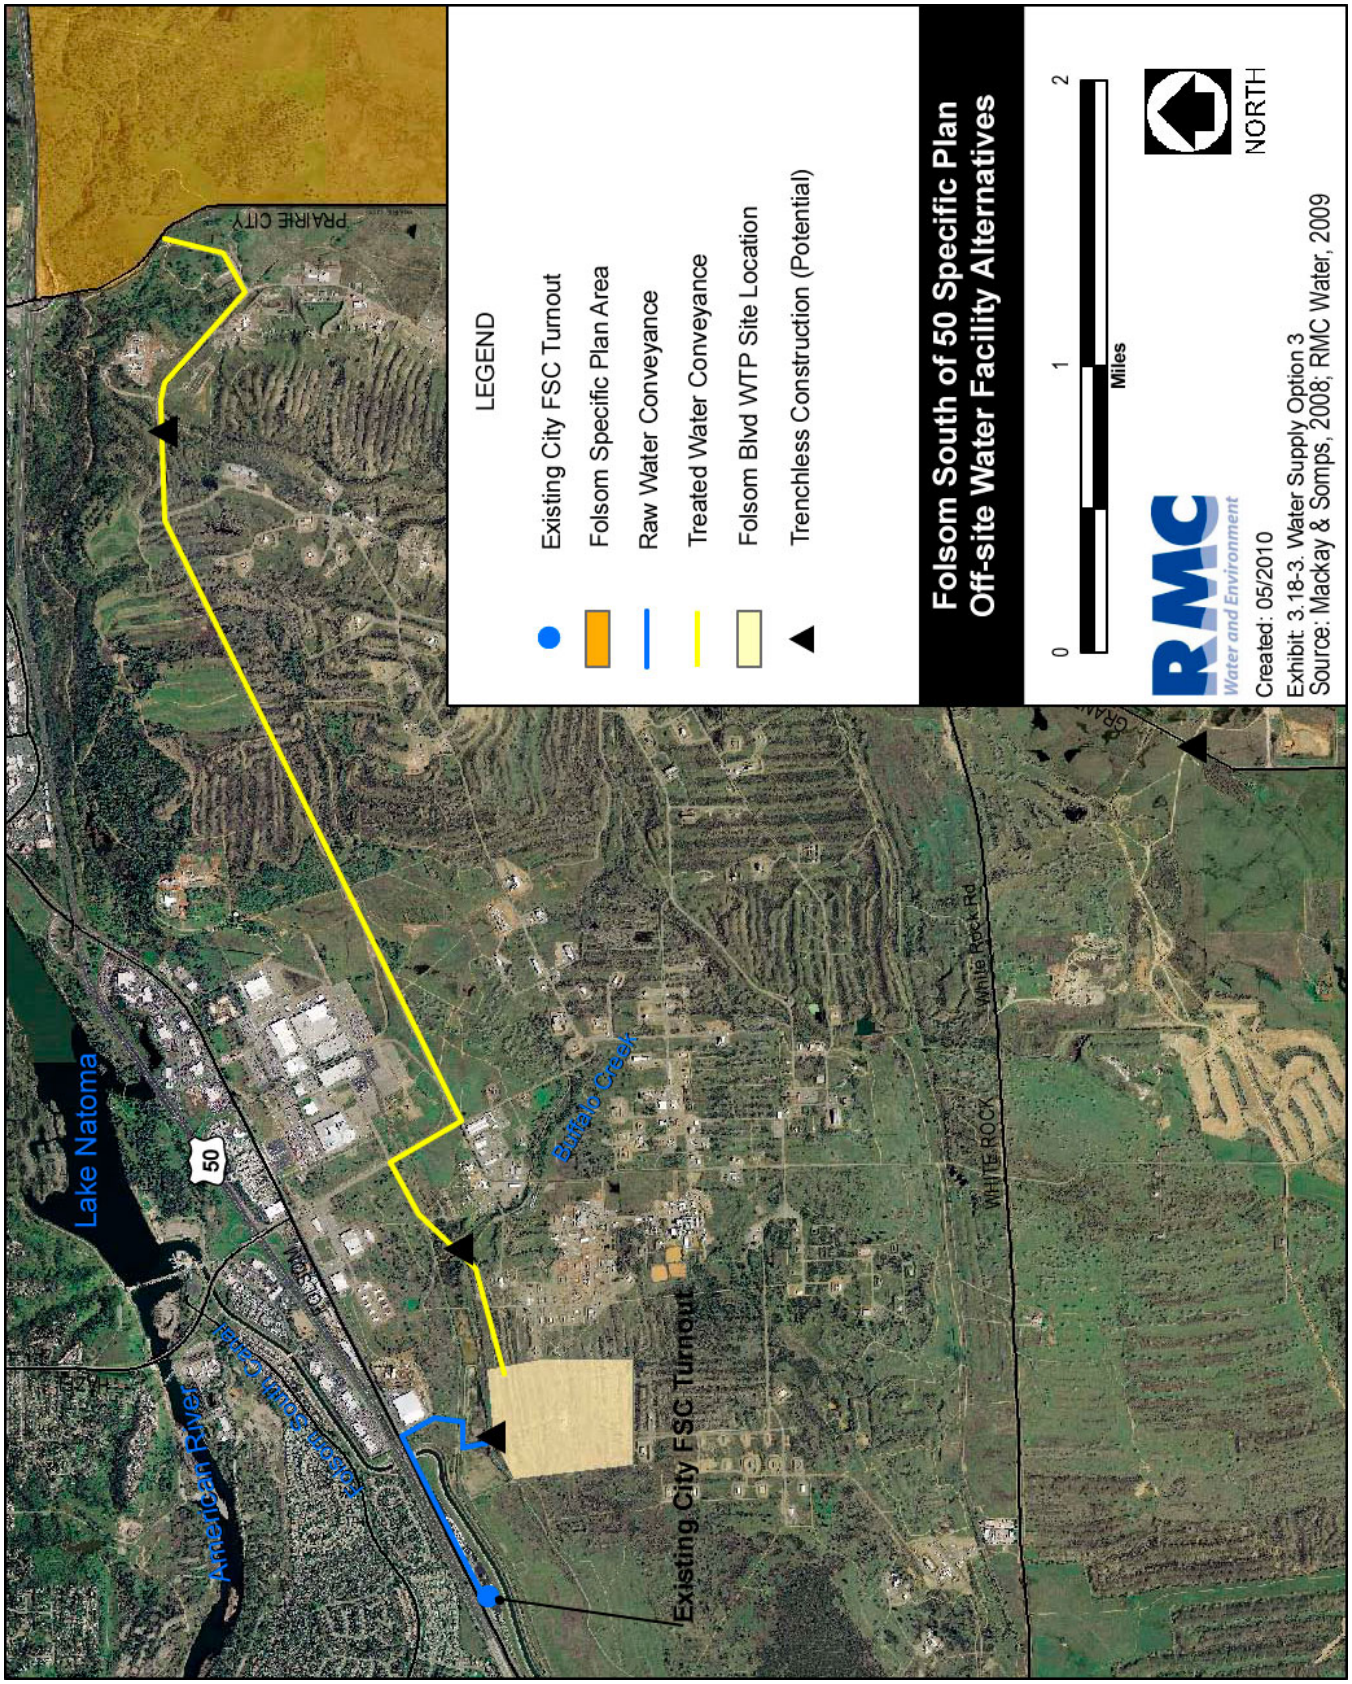
The City currently has rights to 34,000 AFY of surface water for diversion from the American River at Folsom Reservoir or the FSC. These supplies are based on different water rights and contracts as described in the WSA and include:

- 22,000 afy pursuant to a Central Valley Project (CVP) settlement contract, which relates to a pre-1914 appropriative water right, authorizing diversions from Folsom Reservoir or the Folsom South Canal;
- 5,000 afy pursuant to a CVP settlement contract, which relates to a pre-1914 appropriative water right for diversion from Folsom Reservoir or the Folsom South Canal; and
- 7,000 afy from a CVP subcontract with SCWA, which derives from a CVP water service contract held by SCWA, which subcontract entitles the City to divertfrom Folsom Reservoir.

The overall intent of Water Supply Option 3 would be to retrofit the City's existing water infrastructure to reduce these existing losses and use the supplies conserved within the Folsom SPA. The actual repair/replacement requirements are unknown at this time; however, the City expects that much of this work would occur within existing easements and/or roadway ROW. The applicant(s) of the Folsom SPA would fund these improvements up to an agreed upon limit.

Beyond the implementation of a comprehensive retrofit program, the City anticipates that additional supplies may be gained through implementation of possible State conservation laws. In 2009, the California Legislature enacted new law designed to implement the Governor's preference to achieve 20% statewide urban water conservation by 2020. Under new water code section 106008.20, the City will be required to implement conservation measures to reduce its per capita daily water consumption by 2020. The new legislation recognizes that total water use might stay stable, or increase, due to population increases. (New Water Code § 10608.8 (C).) A 20% reduction in the City's demand through a comprehensive water conservation program could net up to 6,800 AFY during normal and wet years when the City receives its full allocation. During dry years and subject to conditions that have yet been satisfied, the City could reduce its diversions pursuant to the Water Forum Agreement. In addition, the City's 7,000 afy CVP subcontract would be subject to Reclamation's development of a municipal & industrial water shortage policy, which is under development. The effect of supply reductions on the yield of the City's possible conservation measures is not known as this time.

Facilities required as part of Option 3 would be similar to those described for Option 2. Conserved water initially would be retained in storage in Folsom Reservoir. Conserved water would be released from Folsom Reservoir and flow downstream to Lake Natoma where it would be diverted and then re-diverted at the City's existing turnout on the FSC; thus no net increase in diversion of stream flows would occur. Surface water would then be conveyed to the Folsom SPA through raw and treated water facilities illustrated in Exhibit 3A.18-3. Option 3 would involve



Water Supply Option 3 – Conservation of Existing Entitlements and Water System Retrofit

Exhibit 3A.18-3

construction of a new 30-inch, raw water connection pipeline from the FSC to a new WTP located south of Folsom Boulevard and east of Sunrise Boulevard (see Exhibit 3A.18-3). The raw water pump station and WTP would be constructed according to the same parameters as described for the Off-site Water Facility Alternatives in Chapter 2, "Alternatives". The 30-inch, treated-water pipeline would follow the same alignment as the proposed Off-Site Water Facility Alternative 4 along the planned Easton Valley Parkway east to the Folsom SPA.

Water Supply Certainty

This water supply option is not the primary water supply because, among other reasons, the City has not determined the firm yield of conservation measures that it could implement and, therefore, is unable to provide confirmation as to whether the net supplies would be sufficient to accommodate the projected demand of 5,600 AFY.

Impact Analysis

Aesthetics

The description of the affected environment for Zone 4 of the "Water" Study Area as provided in Section 3B.1, "Aesthetics – Water," would apply for this water supply option. With implementation of mitigation recommended in Section 3B.1, potentially significant impacts related to exterior finishes and nighttime security lighting would be **similar** to the Off-site Water Facility Alternative 4 and minimized through mitigation identified in Section 3B.1, "Aesthetics – Water," to **less-than-significant** levels.

Air Quality

Air quality impacts resulting from water supply Option 3 would be similar to those identified for Off-site Water Facility Alternative 4 and 4A in Section 3B.2, "Air Quality – Water" and Section 3B.4, "Climate Change - Water." This option would reduce the length of pipeline construction and the associated emissions of criteria air pollutants. However, due to the overlap in the construction of the Off-site Water Facility components, even with the implementation of mitigation similar to that described for Off-site Water Facility Alternative 4 and 4A in the "B", or "Water" sections of Chapter 3, air quality impacts during construction would be **significant and unavoidable**; **similar** to the Proposed Off-Site Water Facility Alternative.

Operational impacts resulting from this option would be **less than significant**, due to impacts **similar** to the Proposed Off-Site Water Facility Alternative.

Biological Resources

The conveyance facilities for this water supply option follow a similar alignment to that of Off-site Water Facility Alternative 4 and 4A following the raw water pipeline from the FSC turnout. Habitats and potentially occurring special status species identified for Off-Site Water Facility Alternatives 4 and 4A could also be expected to occur in close proximity to the conveyance alignment for Option 3. The one major exception is that this water supply option would avoid potential vernal pool impacts along Eagles Nest Road. These impacts are considered **potentially significant** and would require mitigation contained Section 3B.3, "Biological Resources – Water," **similar** to the Proposed Off-site Water Facility Alternative.

Under this option, impact to biological resources in the lower American River would be **less-than-significant** because the City's diversions from the American River would not change and the proposed water supply would be generated by reductions in the City's use of the water that it currently diverts. These changes although not significant would be **greater** than those associated with the Off-site Water Facility Alternatives 4 and 4A by virtue that no changes to flows within the lower American River would occur under the Off-site Water Facility Alternatives. Conversely, impacts to flows within the Sacramento River under this water supply option would be **lesser** when compared to the Off-site Water Facility Alternatives.

Climate Change

Sources of operational emissions associated with this water supply option would be similar to the Off-site Water Facility Alternative 4. As a consequence, the operational analysis under this water supply option would likely be similar to those identified for Off-site Water Facility Alternative 4 in Section 3B.4, "Climate Change - Water." In this context, based on the significance determination for Off-site Water Facility Alternative 1A, the contributions of GHGs to regional and global emissions would be **significant and unavoidable** even after implementation of Mitigation Measures listed in Section 3B.4, "Climate Change-Water," **similar** to the Proposed Off-site Water Facility Alternative.

Cultural Resources

Impacts to cultural resources from water supply Option 3 would be similar to those identified for Off-site Water Facility Alternative 4 and 4A in Section 3B.5, "Cultural Resources - Water." With implementation of mitigation **similar** to that described for Off-site Water Facility Alternative 4 and 4A in the Cultural Resources – Water,", **potentially significant** impacts to historical and archaeological resources would be reduced to a less-than-significant level.

Environmental Justice

No low-income or minority pollutions are identified along the conveyance alignment or WTP for this water supply option and therefore **no impacts** would occur; **similar** to the Proposed Off-site Water Facility Alternative.

Geology, Soils, and Paleontological Resources

Issues related to soils and geology under water supply Option 3 would similar to those identified for Off-site Water Facility Alternative 4 and 4A in Section 3B.7, "Geology, Soils and Paleontological Resources - Water." Similar to the Off-site Water Facility Alternatives, this water supply option would not interfere with the availability of any locally or regionally mapped mineral resource area, but could be impacted by localized soil and geologic conditions. Additionally, the conveyance alignment under this option could encounter paleontological impacts at its eastern extent. With mitigation **similar** to that described for the Off-site Water Facility Alternatives in the Section 3B.7, "Geology, Soils and Paleontological Resources - Water," **potentially significant** soils, geology, and paleontological impacts would be reduced to a less-than-significant level.

Hazards and Hazardous Materials

Public health and safety impacts resulting from Option 3 would be similar to those identified for Off-site Water Facility Alternative 4 and 4A in Section 3B.8, "Hazards and Hazardous Materials - Water." With mitigation **similar** to that described for Off-site Water Facility Alternative 4 and 4A in the Section 3B.8, "Hazards and Hazardous Materials – Water," **potentially significant** impacts to public health and safety would be reduced to a less-than-significant level.

The water quality within the Lower American River meets all standards for drinking water and, therefore, this source water supply is suitable for consumptive use, and because this option would include construction of a WTP, the impact related to potable water quality would be less-than-significant and similar to the Proposed Off-site Water Facility Alternative.

Hydrology, Water Quality, and Groundwater

Water Supply Option 3 would result in no increase in the City's total entitlement to surface water from the American River. In addition, this option could entail minor benefits through the addition of flows to a segment of the American River between Folsom Reservoir and the FSC. Under existing conditions, the City's supplies are

diverted from an intake located at Folsom Reservoir. The environmental impacts of the City's existing diversions on American River were assessed in three previous EIRs:

- Environmental Impact Statement (EIS)/EIR for CVP Water Supply Contracts under Public Law 101-514 (Section 206) ("Fazio Water"; U.S. Bureau of Reclamation [USBR] et al. 1997; SCH# 1993042023)— available at Sacramento County Water Agency, 827 7th Street, Room 301, Sacramento, CA 95814.

- EIR for Water Forum Proposal (EDAW and SWRI 1999; SCH# 95082041)— available at Sacramento County Department of Environmental Review and Assessment (DERA) office, 827 7th Street, Room 220, Sacramento, CA 95814.

- EIR for City's Natoma Pipeline Replacement and Folsom Water Treatment Plant Expansion Project (City of Folsom 1998; SCH# 97042005)—available at Folsom Public Works Department, 50 Natomas Street, Folsom, CA 95630.

Impacts to hydrology and water quality as a result of constructing a new WTP/pump station, pipelines, and other facilities would be similar to those identified for the Off-site Water Facility Alternative 4 and 4A. As a result, the implementation of mitigation required in Section 3B.9, "hydrology and Water Quality – Water," would be required to minimize potential construction and operational effects to local water quality and local drainage.

Land Use and Agricultural Resources

The conservation of existing surface water entitlements from the American River would generally be consistent with the Water Forum Agreement, the State's Water Plan, and the City's General Plan. Although the use of the City's existing water supplies for new growth south of U.S. 50 is generally discouraged by Section 7.04 of the City's Charter (or Measure W), there are several important distinctions to consider. First, under this water supply option, the SPA applicants would fund the retrofit improvements within the City's existing water service area and, therefore, these costs of these improvements would not be funded by existing rate payers. Secondly, the net water supplies gained under this option would come from conservation either through improvements within the City's water distribution system or as mandated by new state laws. As a result, existing residences would not be required to reduce water use or incur costs specifically to provide water for the SPA. Based on these considerations, this water supply option would not conflict with existing plans and policies adopted for the purposes of mitigating a significant environmental effect and the impact is considered **less-than-significant**. These impacts would be **lesser** when compared to the Proposed Off-site Water Facility Alternative.

This alternative would avoid impacts related to the cancellation of an existing Williamson Act Contract and would result in **no impact**; hence, impacts under this options would be **lesser** than the Proposed Off-site Water Facility Alternative.

Noise

Construction and operational noise impacts resulting from Option 3 would be similar to those identified for Off-site Water Facility Alternative 4 and 4A in Section 3B.11, "Noise - Water." With the implementation of mitigation **similar** to that described for Off-site Water Facility Alternative 4 and 4A in Section 3B.11, "Noise - Water," **potentially significant** noise impacts from construction and operation of this option would be reduced to a less-than-significant level.

Recreation

Under Option 3, minor additions to flows within the Lower American River, between Folsom Reservoir and the FSC, could be anticipated thereby benefiting existing rafting and boating opportunities. Compared to existing conditions, no change in surface water conditions below Nimbus Dam would be expected. These impacts would be **less-than-significant** and **similar** to the Proposed Off-site Water Facility Alternative.

Traffic and Transportation

Impacts to traffic and alternative forms of transportation under Option 3 would be less than those identified for Off-site Water Facility Alternative 4 and 4A in Section 3B.15, "Traffic and Transportation - Water." The primary reason for this reduction in the level of impact is attributed to the location of the planned facilities under this option, which coincide with planned roadway facilities that have yet to be constructed. Mitigation similar to that described for Off-site Water Facility Alternative 4 and 4A in the "B", or "Water" sections of Chapter 3 would still be required to minimize impacts to traffic circulation along Prairie City Road to a less-than-significant level.

Utilities and Service Systems

Impacts to public services and utilities under Option 3 would be similar to those identified for Off-site Water Facility Alternative 4 and 4A in Section 3B.16, "Utilities and Service Systems - Water." With implementation of mitigation **similar** to that described for Off-site Water Facility Alternative 4 and 4A in Section 3.16, "Utilities and Service Systems – Water," **potentially significant** impacts to public services and utilities would be reduced to a less-than-significant level.

Option 3 Conclusion

In light of the fact that the City is currently developing its strategy for complying with 2009 water conservation legislation, the City currently cannot estimate the yield of conservation measures or identify specifically what actions it would need to take to implement those measures. The City therefore has not determined how Measure W would apply to such a program or the extent to which such a program could satisfy water demands in the Folsom SPA.

Table 3A.18-15 provides a summary comparison of the environmental impacts for each of the Water Supply Options in relation to the Proposed Off-site Water Facility Alternative.

Table 3A.18-15
Summary Comparison of the Water Supply Options to the Proposed Off-site Water Facility Alternative

Impact Summary	CEQA Water Supply Options		
	Water Supply Option 1	*Water Supply Option 2*	*Water Supply Option 3*
3B.1 Aesthetics – Water			
Impact 3B.1-1. Substantial Adverse Effect on a Scenic Vista. Implementation of the Off-Site Water Facility Alternatives would not result in the degradation of the visual quality of a scenic vista.	S	S	S
Impact 3B.1-2. Substantial Degradation of Existing Visual Character or Quality of the "Water" Study Area. Implementation of the Off-Site Water Facility Alternatives could substantially degrade the existing visual character or quality of the "Water" Study Area and its surroundings.	S	S	S
Impact 3B.1-3. Creation of a New Source of Substantial Light or Glare that would Adversely Affect Day or Nighttime Views in the "Water" Study Area. Implementation of the Off-Site Water Facility Alternatives would create new sources of substantial light or glare, which could adversely affect day or nighttime views in the "Water" Study Area.	S	S	S

Table 3A.18-15
Summary Comparison of the Water Supply Options to the Proposed Off-site Water Facility Alternative

Impact Summary	CEQA Water Supply Options		
	Water Supply Option 1	*Water Supply Option 2*	*Water Supply Option 3*
3B.2 Air Quality – Water			
Impact 3B.2-1. Generation of Construction Emissions of NO_X and PM_{10}. Construction of the Off-Site Water Facility Alternatives would produce construction-generated emissions of NO_X, an ozone precursor, and fugitive PM_{10} dust would exceed SMAQMD-recommended thresholds and would substantially contribute to emissions concentrations that exceed the NAAQS and CAAQS. Thus, project-generated, construction-related emissions of criteria air pollutants and precursors could violate or contribute substantially to an existing or projected air quality violation and/or expose sensitive receptors to substantial pollutant concentrations.	S	S	S
Impact 3B.2-2. Generation of Long-Term Operational (Regional) Emissions of ROG, and NO_X. Operational area- and mobile-source emissions from implementation of the Off-site Water Facility Alternatives would not exceed the SMAQMD-recommended threshold of 65 lb/day for ROG and NO_X.	S	S	S
Impact 3B.2-3. Exposure of Sensitive Receptors to Short- and Long-Term Emissions of Toxic Air Contaminants. Implementation of the Off-Site Water Facility Alternatives could expose sensitive receptors to short- and long-term emissions of TACs from on-site stationary sources.	S	S	S
3B.3 Biological Resources – Water			
Impact 3B.3-1. Loss and Degradation of Waters of the U.S., including Wetlands, and Waters of the State. Construction of the Off-Site Water Facility Alternatives has the potential to result in substantial adverse effects to Federally and state-protected wetlands as defined by Section 404 of the Clean Water Act (including, but not limited to vernal pools and seasonal wetlands) through direct fill or excavation, hydrological interruption, or other indirect impacts. Wetlands, Waters of the State, and other waters of the U.S. that would be affected by implementation of the Off-site Water Facility Alternatives include seeps, vernal pools, seasonal wetlands and seasonal wetland swales, drainage channels, ditches, and ponds.	S	S	S
Impact 3B.3-2. Loss and Degradation of Habitat for Special-Status Wildlife Species and Potential Direct Take of Individuals. The Off-Site Water Facility Alternatives have the potential to result in a substantial adverse effect, either directly or through habitat modifications, on species identified as a candidate, sensitive, or special-status by DFG, NMFS, and USFWS. Impacts could include loss and degradation of habitat for several special-status wildlife species or take of listed species, including vernal pool invertebrates, valley elderberry longhorn beetle, and Swainson's hawk.	S	S	S
Impact 3B.3-3. Potential Loss or Degradation of Special-Status Plant Populations and Habitat. Implementation of the Off-site Water Facility Alternatives could result in direct removal of special-status plants, if they are present, through loss of suitable habitat or degradation of suitable habitat due to site alteration.	S	S	S

Table 3A.18-15
Summary Comparison of the Water Supply Options to the Proposed Off-site Water Facility Alternative

Impact Summary	CEQA Water Supply Options		
	Water Supply Option 1	*Water Supply Option 2*	*Water Supply Option 3*
Impact 3B.3-4. Loss of Sensitive Natural Communities (Not Already Covered under Other Impacts). Construction and operation of the Off-site Water Facility Alternatives has the potential to have a substantial adverse effect on local riparian and woodland habitats. These are natural communities considered sensitive by state and local resource agencies and require consideration under CEQA.	S	S	S
Impact 3b.3-5. Loss Of Individual Oak Trees. Implementation of the Off-Site Water Facility Alternatives could result in the removal of oak woodland and individual oak trees meeting the criteria for protection under Folsom Municipal Code and the Sacramento County Tree Ordinance.	S	S	S
Impact 3B.5-6. Potential Interference with Wildlife or Fisheries Movement. Construction and operation of the Off-Site Water Facility Alternatives has the potential to interfere substantially with the movement of native resident or migratory fish or within established native resident or migratory wildlife corridors.	S	S	S
Impact 3B.5-7. Potential Conflict with Habitat Conservation Plans. Construction of the Off-Site Water Facilities has the potential to conflict with the provisions of an adopted Habitat Conservation Plan or Natural Community Conservation Plan.	S	S	S
3B.4 Climate Change - Water			
Impact 3B.4-1. Generation of Short- and Long-term Increases in Greenhouse Gases. Construction and operation of the Offsite Water Facility Alternatives would result in a net increase in greenhouse gas emissions, which would contribute considerably to cumulative GHG emissions.	S	S	S
Impact 3B.4-2. Effects of Climate Change on the Off-site Water Supply Facilities. Global climate change could result in effects on water quality or water supplies proposed as part of the Off-site Water Facility Alternatives.	S	S	S
3B.5 Cultural Resources – Water			
Impact 3B.5-1. Possible Destruction of or Damage to Known Prehistoric and Historic-Era Cultural Resources from Ground-Disturbance or Other Construction-Related Activities. Construction activities associated with the Off-site Water Facility Alternatives could result in the destruction of or damage to known prehistoric and historic-era cultural resources that are potentially eligible for or listed on the CRHR or NRHP.	S	S	S
Impact 3B.5-2. Possible Destruction of or Damage to Previously Undiscovered Cultural Resources from Ground-Disturbance or Other Construction-Related Activities. Construction activities during project implementation could result in the destruction of or damage to "significant" (under CEQA) undiscovered cultural resources.	S	S	S
Impact 3B.5-3. Possible Destruction of or Damage to Interred Human Remains during Construction. Ground-disturbing activities could inadvertently disinter and/or destroy buried human skeletal remains	S	S	S

	Water Supply Option 1	*Water Supply Option 2*	*Water Supply Option 3*
3B.6 Environmental Justice – Water			
Impact 3B.6-1. Potential Effects on Minority Populations. Implementation of the Off-site Water Facility Alternatives would not create a disproportionate placement of adverse environmental impacts on minority communities.	S	S	S
Impact 3A.6-2. Potential Effects on Low-Income Populations. Project implementation would not create a disproportionate placement of adverse environmental impacts on low-income populations.	S	S	S
3B.7 Geology, Soils, and Paleontological Resources – Water			
Impact 3B.7-1. Possible Risks to People and Structures Caused by Strong Seismic Ground Shaking. Zone 4 of the "Water" Study Area is located in an area of generally low seismic activity; however, structures constructed as part of the Off-site Water Facility Alternatives could be subject to seismic ground shaking from an earthquake along active faults in the Sierra Nevada.	S	S	S
Impact 3B.7-2. Construction-Related Erosion. Construction activities during implementation of the Off-site Water Facility Alternatives would involve grading and movement of earth in soils subject to wind and water erosion hazard.	S	S	S
Impact 3B.7-3. Unstable Geologic Conditions. The Off-Site Water Facility Alternatives could be located on a geologic unit or soil that is unstable, or that could become unstable as a result of the Off-Site Water Facilities.	S	S	S
Impact 3B.7-4. Exposure to Potential Hazards from Problematic Soils. The Off-Site Water Facility Alternatives could encounter expansive or corrosive soils thereby subjecting related structures to potential risk of failure.	S	S	S
Impact 3B.7-5. Possible Damage of or Destruction to of Previously Unknown Unique Paleontological Resources during Construction-Related Activities. Construction of the Off-Site Water Facility Alternatives could directly or indirectly destroy a unique paleontological resource or site.	S	S	S
3B.8 Hazards and Hazardous Materials – Water			
Impact 3B.8-1. Accidental Spill from Routine Transport, Use, or Disposal of Hazardous Materials. Accidental spills of hazardous materials could result during routine transport, use, or disposal activities as part of the implementation of the Off-Site Water Facility Alternatives.	S	S	S
Impact 3B.8-2. Create Accident Conditions Involving Potential Release of Hazardous Materials. Construction and operation of the Off-Site Water Facilities could create a significant hazard to the public or the environment through reasonably foreseeable upset and accident conditions involving the likely release of hazardous materials into the environment.	S	S	S
Impact 3B.8-3. Introduction of Drinking Water Contaminants. Operation of the Off-Site Water Facility Alternatives would not create a significant public health risk through the introduction of contaminants into a drinking water supply at concentrations with known adverse health effects.	G	S	S

Table 3A.18-15
Summary Comparison of the Water Supply Options to the Proposed Off-site Water Facility Alternative

Impact Summary	CEQA Water Supply Options		
	Water Supply Option 1	*Water Supply Option 2*	*Water Supply Option 3*
Impact 3B.8-4. Use of Hazardous Materials within One-Quarter Mile of Schools. Operation of the Off-Site Water Facilities could emit hazardous emissions or handle hazardous or acutely hazardous materials, substances, or waste within one-quarter mile of an existing or proposed school.	S	S	S
Impact 3B.8-5. Create a Significant Hazard to the Public or the Environment. Construction of the Off-Site Water Facilities could encounter one or more sites listed as containing hazardous materials or wastes and, as a result, could create a significant hazard to the public or the environment.	S	S	S
Impact 3B.8-6. Impair or Interfere with an Adopted Emergency Response Plans or Emergency Evacuation Plans. Implementation of the Off-Site Water Facilities would impair implementation of or physically interfere with an adopted emergency response plan or emergency evacuation plan.	S	S	S
Impact 3B.8-7. Exposure to Wildland Fire Hazards. Implementation of the Off-Site Water Facilities could expose people or structures to a significant risk of loss, injury or death involving wildland fires.	S	S	S
3B.9 Hydrology and Water Quality – Water			
Impact 3B.9-1. Potential Temporary, Short-Term Construction-Related Drainage and Water Quality Effects. Construction of the Off-Site Water Facilities could generate discharges to surface water resources that could potentially violate water quality standards or waste discharge requirements.	S	S	S
Impact 3B.9-2. Exceedance of Surface Water Quality Standards during Operation. The operation of the Off-Site Water Facilities could result in changes to the quality of surface water resources that could potentially violate water quality standards or waste discharge requests.	L	S	S
Impact 3B.9-3. Alteration of Drainage Patterns Resulting in Off-Site Flooding and/or Erosion. The Off-Site Water Facilities could result in the alteration of existing drainage patterns thereby increasing the rate or amount of surface runoff in a manner that could result in substantial flooding and/or erosion or siltation on- or off-site.	S	S	S
Impact 3B.9-4. Changes to Flow within the Sacramento River. The Off-Site Water Facilities could result in adverse effects to existing flows within the Sacramento River.	L	S	L
Impact 3B.9-5. Exceed Drainage Capacity and Contribute Sources Polluted Runoff. The Off-Site Water Facilities could create or contribute runoff water which would exceed the capacity of existing or planned stormwater drainage systems or provide substantial additional sources of polluted runoff.	S	S	S
Impact 3B.9-6. Impede or Redirect Flood Flows. The Off-Site Water Facilities could place structures within a 100-year flood hazard area, which would impede or redirect flood flows	S	S	S
Impact 3B.9-7. Inundation from Flooding or Mudflows. The Offsite Water Facility Alternatives would not expose people or structures to a significant risk of loss, injury or death involving inundation by flooding, including flooding as a result of the failure of a levee or dam, seiche, or tsunami or inundation by mudflows.	S	S	S

Summary Comparison of the Water Supply Options to the Proposed Off-site Water Facility Alternative

Impact Summary	CEQA Water Supply Options		
	Water Supply Option 1	*Water Supply Option 2*	*Water Supply Option 3*
3B.10 Land Use and Agricultural Resources - Water			
Impact 3B.10-1. Conflict with Applicable Agency Plans, Policies, or Regulations. Implementation of the Off-site Water Facility Alternatives could conflict with an applicable land use plan, policies, or regulations adopted for the purpose of avoiding or mitigating an environmental effect.	S	S	L
Impact 3B.10-2. Conversion of Important Farmland to Nonagricultural Uses. Implementation of the Off-site Water Facility Alternatives could result in the conversion of Prime Farmland, Unique Farmland, or Farmland of Statewide Importance to nonagricultural uses.	S	S	S
Impact 3B.10-3. Cancellation of Existing On-Site Williamson Act Contracts. Construction of the Off-site Water Facility Alternatives could conflict with lands under Williamson Act contracts; thereby potentially resulting in cancellation of those contracts.	S	S	L
Impact 3B.10-4: Potential Temporary Disruptions to Existing Agricultural Operations. Implementation of the Off-site Water Facilities could potentially affect existing agricultural operations and result in a loss in agricultural productivity.	S	S	S
3B.11 Noise – Water			
Impact 3B.11-1. Temporary, Short-Term Exposure of Sensitive Receptors to Increased Equipment Noise from Project Construction. The Off-Site Water Facility Alternatives could expose persons to or generate noise levels in excess of applicable City and County standards.	S	S	S
Impact 3B.11-2 Exposure to and/or Generation of Groundborne Vibration. The Off-Site Water Facilities could expose persons to or generate excessive groundborne vibration or groundborne noise levels.	S	S	S
Impact 3B.11-3. Permanent Increase in Ambient Noise Levels. The Off-Site Water Facility Alternatives could create a substantial permanent increase in ambient noise levels in the vicinity of new pumping facilities.	S	S	S
3B.12 Parks and Recreation – Water			
Impact 3B.12-1. Temporary Disruptions to Existing Recreational Facilities and Opportunities. Implementation of the Off-Site Water Facility Alternatives could temporarily disrupt trail, golf course, or park facility access.	L	S	S
Impact 3B.12-2. Effects to Water-Oriented Recreational Facilities and Opportunities. Implementation of the Off-Site Water Facility Alternatives would not cause an adverse change in river flows or lake elevations that could result in substantial changes to existing recreational opportunities.	S	S	S
3B.15 Traffic and Transportation – Water			
Impact 3B.15-1. Temporary and Short-Term Reduction in Roadway Capacity during Construction. Off-Site Water Facility Alternatives construction could result in temporary reductions in roadway capacities, which could be substantial in relation to existing volume-to-capacity ratios on local roadways and congestion at intersections.	S	S	L

Table 3A.18-15
Summary Comparison of the Water Supply Options to the Proposed Off-site Water Facility Alternative

Impact Summary	CEQA Water Supply Options		
	Water Supply Option 1	*Water Supply Option 2*	*Water Supply Option 3*
Impact 3B.15-2. Exceedance of Established Level of Service Standards for Local Roadways. The implementation of Off-Site Water Facility Alternatives could cause traffic conditions to exceed, either individually or cumulatively, a level of service standard established by the County congestion management agency for designated roads or highways.	S	S	S
Impact 3B.15-3. Increased Traffic Hazards on Local Roadways. Implementation of the Off-Site Water Facility Alternatives could substantially increase hazards on local roadways due to the presence of incompatible uses, such as construction equipment.	S	S	S
Impact 3B.15-4 Possible Inadequate Emergency Vehicle Access. Construction of the Off-Site Water Facilities could result in disruptions to emergency access.	S	S	S
3B.16 Utilities and Service Systems – Water			
Impact 3B.16-1. Generation of Wastewater. The operation of the Off-Site Water Facility Alternatives would generate wastewater that would require off-site conveyance and treatment.	S	S	S
Impact 3B.16-2. Changes in Operation of the Central Valley Project Water Supply Entitlement. The operation of the Off-Site Water Facility Alternatives would not infringe upon the water rights of other legal users of water.	L	S	S
Impact 3B.16-3. Potential Disruption to Existing Utilities and Infrastructure. Construction of the Off-Site Water Facilities has the potential to disrupt existing public and private utilities and infrastructure.	S	S	S
Impact 3B.16-4 Increased Generation of Solid Waste. Construction and operation of the Off-Site Water Facilities would generate solid waste, which could impact the City's ability to comply with solid waste diversion requirements of the state.	S	S	S
Impact 3B.16-5. Potential Inefficient Energy Consumption. Construction and operation of the Off-Site Water Facilities could result in the inefficient consumption of energy thereby adversely affecting current and future energy conservation efforts.	S	S	S
3B.17. Groundwater Resources			
B3.3-1 - The Water Project could generate discharges to and/or contribute to the depletion of groundwater resources thereby potentially directly and indirectly violating water quality standards or waste discharge requests.	G	G	L
B3.3-2 - The Water Project could substantially deplete groundwater supplies or interfere substantially with groundwater recharge such that there would be a net deficit in aquifer volume or a lowering of the local groundwater levels.	G	G	L
B3.3-3 - Groundwater pumping associated with Water Project operations could alter existing surface hydrology.	G	S	S

3A.18.6 WATER SUPPLY CURTAILMENT ANALYSIS

In its *Vineyard* decision, the California Supreme Court indicated that, in some circumstances, a CEQA lead agency should evaluate the environmental impacts that could occur if a land project's development were to be curtailed because not all of the projected water supplies ultimately were implemented. (*Vineyard Area Citizens for Responsible Growth, Inc. v. City of Rancho Cordova* (2007) 40 Cal.4th 412, 434, 444, 447.) For the reasons described below, however, the City cannot conduct such an analysis because it would be speculative to attempt to identify a reduced level to which this project's projected water supplies would be curtailed.

As shown in Tables 3A.18-6, 3A.18-8, 3A.18-10, 3A.18-12 and 3A.18-14, the water supply proposed as part of the Off-Site Water Facility Alternatives has a demonstrated reliability capable of meeting all of the potable and non-potable water demands resulting from implementation of any of the "Land" alternatives considered. That water supply consists of one source – an assignment of a portion of NCMWC's CVP settlement-contract supply – that would be implemented at one time. Accordingly, unlike the water supplies at issue in *Vineyard*, this project is not subject to the risk that initial phases of the proposed land development could be implemented based on a short-term water supply, but then full development of the project could be curtailed if a proposed long-term water supply cannot be implemented. (See *Vineyard*, 40 Cal.4th at pp. 422-424, 436, 438, 444, 447.)

This EIR/EIS has thoroughly investigated the possible environmental impacts of the City taking an assignment of a portion of the NCMWC supply and using it as the water supply for the SPA's development. (See Sections 3B.2 "Air Quality – Water," 3B.3 "Biological Resources – Water," 3B.4 "Climate Change – Water," 3B.8 "Hazards and Hazardous Materials – Water," 3B.9 "Hydrology and Water Quality – Water," 3B.10 "Land Use and Agriculture – Water," 3B.11 "Noise – Water," 3B.12 "Recreation – Water," 3B.16 "Utilities – Water," and 3B.17 "Groundwater – Water," of Chapter 3, Environmental Analysis, and Sections 4.1 "Cumulative Impacts, 4.2 "Growth Inducing Impacts," and 4.5 "Significant and Unavoidable Adverse Impacts" of Chapter 4, Other Statutory Requirements) It is possible, however, that, as a result of future regulatory actions, climate change, natural disasters or other events, the amount of assigned NCMWC water that could be delivered to the City could be reduced below the proposed 5,600 acre-feet per year minimum supply. At this time, however, the City has no information to indicate when any such reduction might occur, how large the reduction might be or how such a reduction might relate to the proposed development of the SPA. Accordingly, it would be speculative for the City to attempt to identify the environmental impacts that could result from such a water-supply reduction and the resulting curtailment of SPA development. The CEQA Guidelines indicate that a lead agency should terminate its discussion of an impact if the impact is too speculative for evaluation. (15 CCR § 15145.) Accordingly, the City has not attempted to analyze what environmental impacts might occur if SPA development were curtailed as a result of a reduction in the project water supply.

This page intentionally left blank.

4 OTHER STATUTORY REQUIREMENTS

4.1 CUMULATIVE IMPACTS

4.1.1 INTRODUCTION

This EIR/EIS provides an analysis of overall cumulative impacts of the Folsom South of U.S. 50 Specific Plan project (which includes both land use changes ["Land" components] and water supply ["Water" components]) taken together with other past, present, and probable future projects producing related impacts, as required by the State CEQA Guidelines (14 California Code of Regulations [CCR] Section 15130) and "reasonably foreseeable" future projects under NEPA implementing regulations (40 Code of Federal Regulations [CFR] 1508.7). The purpose of this analysis is twofold: first, to determine whether the overall long-term impacts of all such projects would be cumulatively significant and second, to determine whether the Folsom South of Highway 50 Specific Plan project itself would cause a "cumulatively considerable" (and thus significant) *incremental* contribution to any such cumulatively significant impacts. (See the State CEQA Guidelines [CCR Sections 15064(h), 15065(c), 15130(a), 15130(b), and 15355(b)] In other words, the required analysis first creates a broad context in which to assess the project's incremental contribution to anticipated cumulative impacts, viewed on a geographic scale well beyond the project site itself. The analysis then determines whether the project's incremental contribution to any significant cumulative impacts from all projects is itself significant (i.e., "cumulatively considerable" in CEQA parlance).

Cumulative impacts are defined in the State CEQA Guidelines (CCR Section 15355) as "two or more individual effects which, when considered together, are considerable or which compound or increase other environmental impacts." A cumulative impact occurs from "the change in the environment which results from the incremental impact of the project when added to other closely related past, present, and reasonably foreseeable probable future projects. Cumulative impacts can result from individually minor but collectively significant projects taking place over a period of time" (CCR Section 15355[b]).

Consistent with the State CEQA Guidelines (CCR Section 15130[a]), the discussion of cumulative impacts in this EIR/EIS focuses on significant and potentially significant cumulative impacts. The State CEQA Guidelines (CCR Section 15130[b]) state that:

> The discussion of cumulative impacts shall reflect the severity of the impacts and their likelihood of occurrence, but the discussion need not provide as great detail as is provided for the effects attributable to the project alone. The discussion should be guided by the standards of practicality and reasonableness, and should focus on the cumulative impact to which the identified other projects contribute rather than the attributes of other projects which do not contribute to the cumulative impact.

The Council on Environmental Quality (CEQ) regulations implementing provisions of NEPA define cumulative impacts as "the impact on the environment which results from the incremental impact of the action when added to other past, present, and reasonably foreseeable future actions regardless of what agency (Federal or nonFederal) or person undertakes such other actions" (40 CFR 1508.7). Cumulative effects can result from individually minor, but collectively significant, actions over time (40 CFR 1508.8). They are caused by the incremental increase in total environmental effects when the evaluated project is added to other past, present, and reasonably foreseeable future actions. Cumulative impacts can thus arise from causes that are totally unrelated to the project being evaluated, and the analysis of cumulative impacts looks at the life cycle of the effects, not the project at issue.

Where feasible, mitigation measures for cumulative impacts are provided along with the analysis of each issue area in Section 4.1.7 below. In those cases where project-specific mitigation measures would reduce the cumulative level of significance, those mitigation measures are identified.

The cumulative impacts of implementing the Proposed Project or any of the other four action alternatives for "Land" or the Preferred Alternative or any of the other action alternatives for "Water" would be substantially similar; therefore, this cumulative analysis uses the term "project" to refer to the action alternatives under both the "Land" and "Water" components. The cumulative impacts of adopting the No Project Alternative, which could entail construction of up to 44 rural residences under the existing Sacramento County land use and zoning (i.e., Ag-80) without any water conveyance facilities or water treatment plants, have already been analyzed as part of the Sacramento County General Plan EIR (1993), which is incorporated herein by reference.

4.1.2 PROJECTS CONTRIBUTING TO POTENTIAL CUMULATIVE IMPACTS

The State CEQA Guidelines identify two basic methods for establishing the cumulative environment in which the project is to be considered: the use of a list of past, present, and probable future projects (the "list approach") or the use of adopted projections from a general plan, other regional planning document, or certified EIR for such a planning document (the "plan approach"). Either of these methodologies also fulfill the NEPA requirements for cumulative impact analysis (Council on Environmental Quality 1997). For this EIR/EIS, the list and plan approach have been utilized to generate the most reliable future projections possible.

The Folsom South of U.S. 50 Specific Plan project is comprised of several components, including land use changes ("Land" components) and water supply infrastructure ("Water" components). Large-scale development projects in the general vicinity of the "Land" portion of the project are included for known projects within western El Dorado County, eastern Sacramento County, and the City of Folsom. The "Water" portion of the project includes known development and infrastructure projects in Sutter County, the Natomas Basin, and the City of Rancho Cordova and larger statewide planning efforts that could substantially influence cumulative operational conditions along the Sacramento River. Because the Folsom South of U.S. 50 Specific Plan project is a long-term project, and there are innumerably other projects that may be proposed over the lifespan of the project's buildout, the plan approach is also used to ensure that long-term growth throughout the region is considered. Projects and plans included in these two approaches are described below.

4.1.3 CUMULATIVE CONTEXT

Sacramento County, El Dorado County, and Sutter County as a whole are facing numerous regional issues pertaining to air quality degradation, traffic congestion, biological habitat loss, water quality degradation, and other urban-related environmental changes, which are discussed in greater detail below.

SACRAMENTO COUNTY

Sacramento County encompasses approximately 775 square miles in the middle of the 400-mile-long Central Valley, which is California's prime agricultural region. Sacramento County is bordered by Contra Costa and San Joaquin Counties on the south, Amador and El Dorado Counties on the east, Placer and Sutter Counties on the north, and Yolo and Solano Counties on the west. Sacramento County extends from the low delta lands between the Sacramento and San Joaquin Rivers north to about 10 miles beyond the State Capitol and east to the foothills of the Sierra Nevada. The southernmost portion of Sacramento County has access to the San Francisco Bay via the Sacramento River. Sacramento County lies at the geographic center of the region and spans both agricultural land uses as well as the most urbanized areas of the region. The geographic boundaries of Sacramento County include seven incorporated cities: Sacramento, Folsom, Rancho Cordova, Citrus Heights, Elk Grove, Galt, and Isleton.

The highest densities of employment and residential uses are located in the urban core of the city of Sacramento. Two of the three regional employment centers are located in Sacramento County, one in downtown Sacramento and the more recent along U.S. Highway 50 (U.S. 50) in the cities of Rancho Cordova and Folsom. Land uses north of the American River are primarily suburban residential with concentrations of commercial and employment uses along major transportation routes. The southern end of the region (e.g., south Sacramento, the unincorporated Vineyard community, the cities of Elk Grove and Galt) is predominantly residential, with the latter three areas at

fairly low-suburban to rural densities. The Cosumnes River floodplain and existing agricultural operations separate the cities of Elk Grove and Galt. The southeast county (outside of existing cities and the county Urban Services Boundary [USB]) is in agricultural use with pockets of rural residential communities.

Growth in Sacramento County is occurring and is projected to occur primarily in the cities of Elk Grove and Rancho Cordova and in the community of Natomas, which are the only remaining areas of the county within the USB where land is available.

New residential development is expected to result from buildout of vacant and underutilized parcels; planned communities, including Elverta, East Antelope, Vineyard Springs, North Vineyard Station, and Florin Vineyard Gap; mixed-uses in commercial corridors; and the West of Watt, Easton, Jackson Highway Corridor, and Grant Line East New Growth Areas. Approximately 113,000 housing units could be developed from buildout of these areas (Sacramento County 2009:2-12).

According to the Sacramento Area Council of Government's (SACOG's) Sacramento Region Blueprint, the unincorporated portion of Sacramento County will grow by nearly 100,000 new jobs and 100,000 new housing units by 2030, indicating that this trend is likely to continue (Sacramento County 2009:2-9). Accommodating the projected employment and the new residents will not only require more housing, but will also necessitate additional jobs, stores, human services, transportation system capacity, public facilities, and municipal and countywide services. The county population has grown from 1,041,219 in 1990 to 1,223,499 in 2000 (U.S. Census Bureau 2000b), and the population of the county as of January 1, 2008, was estimated to be 1,433,187 (California Department of Finance [DOF] 2009).

EL DORADO COUNTY

El Dorado County encompasses approximately 1,790 square miles with the waters of Lake Tahoe and Folsom Lake covering 65 square miles of this total area. The physical environment of El Dorado County has an important influence on its land use and development patterns. The most important physical features affecting development are the Sierra Nevada mountain range, U.S. 50, large areas of the county that are dominated by forestland, and Lake Tahoe. (El Dorado County 2003: 5.1-1.)

The Sierra Nevada divides El Dorado County into two distinct topographic areas—the west slope and Lake Tahoe Basin. The west slope extends from the Sacramento County line on the west to the summit of the Sierra Nevada on the east and contains most of the developed land in the county. The Lake Tahoe Basin extends from the eastern side of the Sierra Nevada to the California/Nevada border. This mountainous area is characterized physically by rugged and steep terrain. (El Dorado County 2003: 5.1-1.)

U.S. 50 bisects El Dorado County, traveling east-west from the Sacramento County through Placerville to and past the California/Nevada border just south of Lake Tahoe. Development in the county has closely followed this route, with the densest development in the west. One reason for the clustering of development in the western portion of the county is the vast area of forestland that is in the El Dorado National Forest and privately owned commercial timberland, and steep terrain that covers much of the eastern two-thirds of the county. Major towns and communities along this corridor include El Dorado Hills, Cameron Park, Shingle Springs, Placerville, Pollock Pines, and South Lake Tahoe. In addition, U.S. 50 is a major transportation corridor for residents living in El Dorado County and working in Sacramento County and for recreation-related traffic generated in areas outside of the county. (El Dorado County 2003: 5.1-2.)

Development on the west slope is concentrated near the El Dorado/Sacramento County line and along the U.S. 50 corridor, with several large-scale residential and commercial developments under construction and approved plans for additional future development. The density of residential and commercial development gradually decreases and the amount of open space increases heading east from the foothills to the Sierra Nevada summit. Placerville,

located approximately 15 miles from the county line, is the only incorporated city on the west slope. (El Dorado County 2003: 5.1-1.)

The projected demand for new housing by 2025 is roughly 32,000 units (El Dorado County 2003:4-14). New residential development is anticipated to occur in the western portion of El Dorado County with El Dorado Hills experiencing the largest growth (El Dorado County 2003:4-14). This is due to the proximity to public services and the regional job base. Nonresidential development is also expected to occur in the western parts of El Dorado County where additional household growth is driving growth in employment (El Dorado County 2003:4-20).

According to SACOG's Sacramento Region Blueprint, El Dorado County will grow by nearly 187,000 new jobs and 32,000 new housing units by 2050 (SACOG and Valley Vision 2004a). El Dorado County population has grown from 125,995 in 1990 to 156,299 in 2000 (U.S. Census Bureau 2000a), and the current population of El Dorado County as of January 1, 2009, was estimated to be 180,185 (DOF 2009).

SUTTER COUNTY

Sutter County is situated in the Sacramento Valley, with the southern boundary located approximately 10 miles north of the city of Sacramento. Sutter County comprises 607 square miles of land. It is generally bordered on the west by the Sacramento River, on the east by the Feather and Bear Rivers and Placer County, on the north by Butte County, and on the south by Sacramento County. State Route (SR) 99 extends in a north-south direction through Sutter County and is the primary corridor connecting Sutter County to the region. SR 99 is joined by SR 70 in the southern part of Sutter County, becoming SR 99/70. SR 70 extends north to the cities of Marysville and Oroville. SR 20 is the primary east-west connection through Sutter County. (Sutter County 2008.)

The unincorporated area of Sutter County consists of several rural communities including Meridian, adjacent to the western boundary in the north; Sutter, located in the north-central portion of Sutter County abutting the Sutter Buttes; Robbins, located in the southwest between the Sacramento River and the Sutter Bypass along SR 113; and the communities of Rio Oso, Trowbridge, Nicolaus, and East Nicolaus, all clustered near the convergence of the Bear and Feather Rivers in the southeast portion of Sutter County. (Sutter County 2008.)

In addition to the rural communities, Sutter County includes two incorporated cities: Yuba City and Live Oak. Yuba City is the major urban center within Sutter County and is located along the Feather River in the east-central portion of Sutter County where SR 99 and SR 20 intersect. The city of Live Oak is located in the northeast corner of Sutter County north of the city of Yuba City.

Although residential uses are clustered in the cities and rural communities, approximately 8,800 acres of residential uses are scattered throughout the remainder of Sutter County. Most of these residential uses are located in unincorporated areas surrounding the cities of Yuba City and Live Oak and outside of the boundaries of the rural communities. Other clusters of residential land use occur along major transportation corridors, such as SR 99 and SR 20, as well as along the Sacramento and Feather Rivers and surrounding the Sutter Buttes. Other smaller concentrations of industrial and public areas are also located throughout unincorporated Sutter County, most often near the concentrations of residential uses mentioned above and outside of the rural communities' boundaries. Small clusters of commercial uses exist outside of the cities and rural communities, but in general, these uses occur either within or immediately surrounding these areas. (SACOG 2007.)

Most of the growth in Sutter County has taken place in the cities of Yuba City and Live Oak. Annexations and new development have increased the share of Sutter County's incorporated population from 40% in 1970 to 75% in 2007 (SACOG 2007). SACOG's Sacramento Region Blueprint anticipates 40,000 households and 60,000 jobs in Sutter County between 2000 and 2050. With regard to the Proposed Project, the SACOG Blueprint Preferred Scenario anticipates approximately 20,000 jobs and 8,500 households on 7,420 acres in the south Sutter County area. Sutter County has grown from 64,415 people in 1990 to 78,930 people in 2000 (U.S. Census Bureau 2000). The current population of Sutter County as of January 1, 2009, was estimated to be 95,878 persons (DOF 2009a).

CITY OF FOLSOM

The City of Folsom encompasses approximately 24 square miles within the incorporated boundaries, of which 2.4 square miles are water, primarily accounted for by Folsom Lake. The City is located in north-central California about 20 miles east of Sacramento and approximately 125 miles east of San Francisco. The city is bounded by Folsom Lake to the north, the El Dorado County line to the east, U.S. 50 to the south, and Lake Natoma to the southwest. The city is bisected by the American River, which runs diagonally from northeast to southwest from the Folsom Lake to Lake Natoma. The City limit also extends north of the American River and to the Placer County line north of Folsom-Auburn Road and the Baldwin Reservoir.

The SACOG Blueprint Preferred Scenario anticipates an additional 24,400 households and 31,700 jobs in Folsom between 2000 and 2050 (SACOG and Valley Vision 2004a). The Blueprint assumes the City would have a population of 105,000 by 2050 and most of this growth would be located on vacant land within the current City boundaries and within the SPA. The City population has grown from 29,802 in 1990 to 51,884 in 2000 (U.S. Census Bureau 2000c), and the population of the City as of January 1, 2009, was estimated to be 71,018 (DOF 2009b).

CITY OF RANCHO CORDOVA

The City of Rancho Cordova encompasses approximately 20,000 acres in eastern Sacramento County. The Planning Area for the City of Rancho Cordova consists of the existing incorporated city and a larger study area (approximately 58,190 acres) and was selected based on the city limits and surrounding areas that are anticipated to be incorporated into the city in the future (Rancho Cordova 2006: 3.0-1). The city limits and its Planning Area are generally bordered by the American River on the north, Prairie City Road and the boundary of the 100-year floodplain for the Cosumnes River on the east, Jackson Highway (SR 16) on the south, and Watt Avenue and the City of Sacramento on the west. (City of Rancho Cordova 2006.)

The city is characterized by a wide range of existing land uses, including residential developments, commercial/retail/office uses, industrial uses, and institutional uses. The majority of the commercial, office, and retail uses are located along the Sunrise Boulevard and Folsom Boulevard corridors. Industrial, manufacturing, and distribution facilities are located throughout the city, primarily along Sunrise Boulevard, Jackson Highway (SR 16), Bradshaw Road, and Folsom Boulevard. The Aerojet General Corporation operations are located south of U.S. 50 and east of Sunrise Boulevard. Teichert and Granite have active mining operations north of Jackson Highway (SR 16) between Bradshaw Road and Excelsior Road and Teichert also has operations south of U.S. 50 along Grant Line Road. The most southern portion of the city (i.e., south of SR 16) is characterized with rural residential, agricultural operations, and industrial land uses. (City of Ranch Cordova 2006: 4.1-4.)

The SACOG Blueprint Preferred Scenario anticipates an additional 112,000 households and 144,000 jobs in Rancho Cordova between 2000 and 2050. The Blueprint assumes Rancho Cordova would have a population of over 332,000 people by 2050 and a fairly even mixture of jobs and housing and this growth would occur through development on underutilized lands along and near Folsom Boulevard and lands inside the current Urban Services Boundary (USB). Housing is expected to be primarily single-family detached homes plus multi-family units (attached rowhouses, townhomes, condominiums, and apartments) to ensure housing for the growing population and work force. (SACOG and Valley Vision 2004d.) The city population has grown from 48,731 in 1990 to 53,065 in 2000 (U.S. Census Bureau 2000), and the population of the City as of January 1, 2009, was estimated to be 61,817 (DOF 2009c).

4.1.4 GEOGRAPHIC SCOPE

Different portions of the project would develop on and affect different geographical areas. The following geographic area descriptions are used in this EIR/EIS:

- **Specific Plan Area (SPA):** This refers to the entire area proposed for annexation by the City of Folsom, including U.S. 50 highway right-of-way and interchange areas, for a total of approximately 3,584 acres. Most "On-Site" analyses in the "Land" portion of this EIR/EIS address conditions on the SPA.

- **Off-site Improvements:** This refers to the location of certain off-site improvements required to support the proposed land use changes, including a detention basin west of Prairie City Road; roadway and interchange improvements along U.S. 50 (at Prairie City Road, Oak Avenue, Rowberry Drive, Scott Road, and Empire Ranch Road); a sewer line extension across U.S. 50 to an existing pump station along Iron Point Road; and sewer and roadway extensions into El Dorado Hills.

- **Off-site Water Facilities Study Area:** This refers to the area studied for the various water supply facilities required under the alternatives in the "Water" portion of this EIR/EIS. These facilities include: (1) a point of diversion on the Sacramento River at the Freeport Project, (2) a raw or treated-water booster pump station, (3) a raw or treated-water conveyance pipeline alternative to convey the water to the SPA, and (4) a water treatment plant (WTP) alternative.

The geographic area that could be affected by the "Land" and "Water" portions of the project varies depending on the type of environmental resource being considered. When the impacts of the "Land" and "Water" portions of the project are considered in combination with other past, present, and future projects to identify cumulative impacts, the other projects considered may also vary depending on the type of environmental impacts being assessed. The general geographic area associated with different environmental impacts of the 'Land" and "Water" portions of the project defines the boundaries of the area used for compiling the list of projects considered in the cumulative impact analysis. Table 4-1 presents the general geographic areas associated with the different resources addressed in this EIR/EIS cumulative analysis.

Table 4-1
Geographic Scope of Cumulative Impacts

Resource Issue	Geographic Area	
	Land	Water
Aesthetics	Sacramento County, the City of Folsom, and the community of El Dorado Hills	Sacramento County and the City of Rancho Cordova
Air Quality	Sacramento Federal Ozone Nonattainment Area (includes Sacramento County, Yolo County, the western portion of El Dorado County, and portions of Placer and Solano Counties)	Sacramento Federal Ozone Nonattainment Area (includes Sacramento County, Yolo County, the western portion of El Dorado County, and portions of Placer and Solano Counties)
Biological Resources	Alder Creek, Buffalo Creek, Coyote Creek, and Carson Creek watersheds	Sacramento County
Climate Change	Global, regional, and local (SPA and vicinity)	Global, regional, and local (Off-Site Water Facilities Study Area and vicinity)
Cultural Resources	SPA and Sacramento Region, including El Dorado and Sacramento Counties and the City of Folsom	Sacramento Region, including Sacramento County and the City of Rancho Cordova
Environmental Justice	City of Folsom, Sacramento County, and El Dorado Hills	City of Rancho Cordova and Sacramento County
Geology, Soils, Minerals, and Paleontological Resources	SPA and immediate vicinity	Alternative WTP sites and alternative conveyance pipeline alignments
Hazards and Hazardous Materials	SPA	Alternative WTP sites and alternative conveyance pipeline alignments
Hydrology and Water Quality	South American Groundwater Subbasin, Alder Creek, Buffalo Creek, Coyote Creek, and Carson Creek watersheds and their receiving waters	Alder Creek and Buffalo Creek

Table 4-1
Geographic Scope of Cumulative Impacts

Resource Issue	Geographic Area	
	Land	Water
Groundwater Resources	NA [1]	South American Groundwater Subbasin and North American Groundwater Subbasin
Land Use and Agricultural Resources	Development identified in El Dorado County, Sacramento County, and the City of Folsom	Development identified in Sacramento County and the City of Rancho Cordova
Noise	Immediate project vicinity where effects are localized	Immediate vicinity of alternative WTP sites and alternative conveyance pipeline alignments where effects are localized
Parks and Recreation	Regional and local facilities	Regional and local facilities
Population, Employment, and Housing	Sacramento Region, including El Dorado and Sacramento Counties and the City of Folsom	NA [2]
Public Services	City of Folsom Fire Department, City of Folsom Police Department, and Folsom Cordova Unified School District	NA [2]
Traffic and Transportation	Regional and local facilities	Regional and local facilities
Utilities and Service Systems	Natomas Central Mutual Water Company, Sacramento Regional County Sanitation District, Sacramento Regional Wastewater Treatment Plant, El Dorado Irrigation District, Sacramento Metropolitan Utility District, Kiefer Landfill, PG &E, AT&T, and Comcast	Kiefer Landfill, SMUD, and AT&T

Notes: NA = not applicable; WTP = water treatment plant; SMUD = Sacramento Municipal Utility District; PG&E = Pacific Gas & Electric Company

[1] Groundwater resources under the land portion of the project are included in Section 3A.9, "Hydrology and Water Quality."

[2] The "Water" portion of the project would have no impacts on population, employment, and housing and public services as explained in detail in EIR/EIS Section 3.0, "Affected Environment, Environmental Consequences, and Mitigation Measures."

4.1.5 LIST OF RELATED PROJECTS

The list of past, present, and probable future projects used for this cumulative analysis is restricted to major development projects in eastern Sacramento County, western El Dorado County, and the City of Folsom under the "Land" portion of the project; and major development projects and roadway and water supply infrastructure projects in Sacramento County, Sutter County, the Natomas Basin, and the City of Rancho Cordova under the "Water" portion of the project (as defined above). For the purposes of this discussion, these projects that may have a cumulative effect on the resources in the SPA, the off-site improvements, or the Off-site Water Facilities Study Area will often be referred to as the "related projects." These related projects are identified in Exhibits 4-1 and 4-2 and Tables 4-2 and 4-3 (note that the map numbers identified for each related project in Tables 4-2 and 4-3 correspond with the numbers that appear on the map in Exhibits 4-1 and 4-2, respectively). The analysis of cumulative environmental impacts associated with the "Land" and "Water" portions of the project addresses the potential incremental contributions of the "Land" and "Water" portions of the project in combination with these related projects. The projects listed in Tables 4-2 and 4-3 are not intended to be an all-inclusive list of projects in the region, but rather an identification of larger projects approved or planned in eastern Sacramento County, western El Dorado County, and the Cities of Folsom and Rancho Cordova that may affect the same resources as the Folsom South of U.S. 50 Specific Plan project.

ROADWAY IMPROVEMENT PROJECTS

Roadway improvement projects planned in the Off-site Water Facilities Study Area include the White Rock Road Realignment and Widening Project, Florin Road Widening Project, and the Capital Southeast Connector. Initial improvements for these roadway projects are planned for construction sometime between 2010 and 2012. The approximate locations of these roadway improvements are shown in Exhibit 4-2. As shown, these projects would be constructed within Zone 4 of the Off-site Water Facilities Study Area.

WATER SUPPLY INFRASTRUCTURE PROJECTS

Davis-Woodland Water Supply Project

The Cities of Davis and Woodland in Yolo County are jointly proposing to divert up to approximately 46,000 acre-feet per year (AFY) of surface water from the Sacramento River. The cities are proposing to use an existing diversion/intake facility operated by Reclamation District (RD) 2035. This intake location is located north of Zone 2 in the Off-site Water Facilities Study Area.

Sacramento River Water Reliability Study

The U.S. Bureau of Reclamation (Reclamation) and Placer County Water Agency (PCWA) are proposing the Sacramento River Water Reliability Study (SRWRS), which would consist of a package of water supply infrastructure components, including new or expanded diversion(s) from the Sacramento River, and new or expanded water treatment and pumping facilities, storage tanks, and major transmission and distribution pipelines. The Sacramento River diversion site is situated north of Zone 2 in the Off-site Water Facilities Study Area.

Vineyard Surface Water Treatment Plant

As described in Chapter 2, "Alternatives," the Sacramento County Water Agency (SCWA) is in the initial stages of constructing the Vineyard surface water treatment plant (SWTP) with operation anticipated by 2012. The later phases of construction may potentially overlap with construction of the water portion of the project. The Vineyard SWTP is within Zone 4 of the Off-site Water Facilities Study Area.

Yuba River Accord

The purpose of the Yuba River Accord is to resolve instream flow issues associated with operation of the Yuba Project in a way that protects and enhances lower Yuba River fisheries and local water supply reliability. For discussion purposes, the Yuba Project includes: storage and hydropower facilities located in the Yuba River basin; the riparian corridor along the North Yuba River downstream of New Bullards Bar Dam; the lower Yuba River downstream of Englebright Dam to the confluence with the Feather River; the Yuba County Water Agency (YCWA) Member Unit water service areas; the local groundwater basin; and lands overlying the groundwater basin. In addition, Reclamation and the California Department of Water Resources' (DWR's) goals for the project include obtaining water for CALFED to use for protection and restoration of Sacramento-San Joaquin Delta (Delta) fisheries and for improvements in statewide water supply reliability, including supplemental water for the Central Valley Project (CVP) and State Water Project (SWP). As a state agency party to the Yuba Accord, DWR also would be involved in the purchase of Yuba Project water for use in the Environmental Water Account (EWA) Program (described further below) and for SWP contractor supplies. The flows for the Yuba River Accord may provide up to 60,000 AFY for EWA, in the lower Yuba River (estimated to provide up to 48,000 AF of additional Delta export), and may provide additional water to the CVP and SWP and their contractors in drier years.

The Yuba Accord includes a Fisheries Agreement that contains new minimum in-stream flows for the lower Yuba River that are intended to maintain or increase protection of the river's fisheries resources. To help provide these flows, the YCWA would implement conjunctive use agreements to establish a comprehensive conjunctive use program that would provide for comprehensive management of the surface water and groundwater supplies. The flow schedules are based on water availability, including inflow into New Bullards Bar Reservoir and reservoir carry-over storage. The cumulative analysis acknowledges the existence of these new minimum instream flow requirements on the Lower Yuba River, which contribute to the total flow within the Sacramento River, north of the Natomas Central Mutual Water Company (NCMWC). The Yuba Accord is northeast of Zone 1.

Environmental Water Account

The EWA consists of two primary elements: (1) facilitation of fish population recovery through asset (water) acquisition and management, and (2) use of the acquired assets to replace water deliveries (or supplies) interrupted by changes in CVP/SWP operations. The Preferred Alternative, or the Flexible Purchase Alternative for the EWA, would allow the EWA agencies the ability to acquire up to 600,000 AF of water assets (although the EWA agencies would typically acquire 200,000 to 300,000 AFY, except in years with high fish needs) to address pump reductions and other fish actions, and to compensate the CVP/SWP for water otherwise lost due to those actions.

A Supplement to the Final EIS/EIR (State Clearinghouse No. 1996032083) for the EWA was prepared by DWR and Reclamation in 2007, which provides an evaluation of the effects associated with extending the current EWA through 2011. For the purposes of the cumulative analysis, it is assumed that the EWA would continue as currently established through the 2030 timeframe.

Reclamation/ El Dorado County Water Agency Central Valley Project Water Supply Contract

This project involves a new CVP Municipal and Industrial (M&I) Water Service Contract between Reclamation and the El Dorado County Water Agency (EDCWA) for up to 15,000 AFY. This contract would have a 40-year

term and would be subjects to renewals. EDCWA intends to allocate this new contract water to both El Dorado Irrigation District (EID) and Georgetown Divide Public Utility District (GDPUD) based on these parties individual water needs and timing requests. The cumulative analysis assumes that this surface water supply is allocated to EID or GDPUD under future cumulative conditions and diverted upstream of the Off-site Water Facilities Study Area.

MATHER INTERCEPTOR PROJECT

The Sacramento Regional County Sanitation District (SRCSD) is proposing the installation of a new sewer trunk and pump station project to serve new development with in southern Rancho Cordova. The project currently includes five sewer interceptor alternatives, which would serve the general area north of the Jackson Highway (SR 16) and east of Sunrise Boulevard. Construction is planned for 2009 through 2010. These improvements would overlap with Alternatives 2, 2A, 3, 3A, 4, and 4A of the "Water" portion of the project.

EASTERN SACRAMENTO COUNTY GROUNDWATER REPLACEMENT PROJECT

This project would construct the necessary conveyance and pumping facilities to use remediated groundwater from Aerojet and McDonnell Douglas Corporation (MDC)/Boeing groundwater extraction and treatment (GET) facilities. Following its discharge to local waterways, remediated water from the GET facilities would be diverted by Sacramento County Water Agency (SCWA) and other water purveyors as replacement water for groundwater production capacity lost as a result of contaminated wells that have been taken out of service in Sacramento County and the City of Rancho Cordova, for: (1) new development within eastern Sacramento County; and (2) environmental benefit, namely supplement flows for fishery enhancement and groundwater recharge in the Cosumnes River. The GET water would be diverted at Reclamation's Folsom South Canal (FSC), City of Sacramento Fairbairn WTP Diversion, and the Freeport Project diversion, on the Sacramento River, downstream of the American River confluence. Based on the implementation of this project, groundwater pumped and conveyed from GET facilities is not lost from the basin, but rather diverted by SCWA and delivered to local wholesale and retail water agencies. For the purposes of this cumulative analysis, it is assumed the continuation of the Regional Water Supply Plan (RWSP) estimated at 35,890 AFY.

DEER CREEK HILLS PRESERVE

The Deer Creek Hills Preserve consists of 4,062 acres, bordered by Scott Road to the west and Michigan Bar Road to the east. The Deer Creek Hills Preserve is administered by the Sacramento Valley Conservancy, the County of Sacramento, and State Parks. Land uses at this site include open space, habitat preservation, cattle grazing, and public recreation (Sacramento County 2008a:1-1).

The draft environmental impact report (DEIR) for the Deer Creek Hills Preserve Master Plan (State Clearinghouse Number 200705210) was released on December 12, 2008, for a 45-day public review period. As described in the DEIR, the Deer Creek Hills Preserve project would result in various environmental impacts, most of which would be reduced to a less-than-significant level through implementation of mitigation measures. The only significant and unavoidable impact that would occur is the disturbance of sensitive cultural resources (Sacramento County 2008a:1-1).

TEICHERT QUARRY

The proposed Teichert Quarry would be located approximately 0.9-mile south of the SPA in Sacramento County, south of White Rock Road, east of Grant Line Road, and west of Scott Road. The Teichert Quarry project would be located on approximately 380 acres of the 580-acre site and would include construction of an aggregate processing facility, administration complex, parking areas, on-site access road, and various other stockpiles and processing areas (Sacramento County 2008b:S-1). The Teichert Quarry project includes construction of a public

access road for ingress/egress to the property that would extend from the entrance/exit of the property north approximately one mile to White Rock Road.

The maximum proposed annual aggregate production during the life of the quarry would be 7 million tons per year. A maximum of 6 million tons per year would be distributed directly from the quarry site on haul trucks using the proposed access road. A maximum of 3 million tons and a minimum of 1 million tons per year would be conveyed to the existing Grant Line facility for further processing and sale. Mining would continue for up to 25 years through two mining phases. A total of about 135 million tons of material would be mined over the life of the quarry. At the conclusion of aggregate production, a two- to four-year final reclamation phase would extend the total project lifespan to 27 to 29 years. (Sacramento County 2008b:2.0-6.)

The DEIR for the Teichert Quarry Project was released on August 22, 2008, for a 45-day public review period. The requested entitlements for the Teichert Quarry project are the following: a General Plan Amendment and rezoning, a use permit, a grading permit, a reclamation plan, an encroachment permit, and a development agreement (Sacramento County 2008b:1.0-2). As described in the Teichert Quarry Project DEIR, construction and operation of the quarry would result in a number of environmental impacts, most of which would be reduced to a less-than-significant level through implementation of mitigation measures. Significant and unavoidable impacts associated with the quarry would include: adverse effects on a scenic vista; degradation of the existing visual character of the site and its surroundings; introduction of new sources of substantial light or glare; long-term increases in reactive organic gases (ROG) and oxides of nitrogen (NO_X); increases in traffic from deterioration of levels of service below acceptable levels at roadways or intersections operating at an acceptable level, increases in the volume to capacity ratio at roadways not operating at an acceptable levels of service, and increases in delay by more than five seconds at unsignalized intersections; and potential increases in accidents between haul trucks and cars.

The Teichert Quarry project DEIR includes the following cumulatively significant and unavoidable impacts: alteration of the visual character of the SPA and visual incompatibility with surrounding land uses in the vicinity of the SPA; introduction of new sources of substantial light or glare in the vicinity of the SPA; conversion of agricultural lands to nonagricultural uses; long-term degradation of regional air quality; cumulative impacts on biological resources from buildout of Sacramento County; increases in traffic from deterioration of levels of service below acceptable levels at roadways or intersections operating at an acceptable levels, increases in the volume to capacity ratio at roadways not operating at an acceptable levels of service, increases in density on a segment of U.S. 50 operating at unacceptable levels of service without the Teichert project, and increases in delay by more than five seconds at unsignalized intersections; increases in accidents between haul trucks and cars; and increases in greenhouse gas emissions.

WALLTOWN QUARRY

The proposed Walltown Quarry project would be located south of White Rock Road and east of Scott Road approximately 1.2 miles south of the SPA. The quarry site is approximately 1,360 acres in size and the active mining and processing area would be approximately 613 acres. The quarry project includes a new access road on an existing right of way that would extend from the quarry property north to White Rock Road. The quarry project would generally involve excavation and processing of hard rock aggregate. The project includes a request for a 100-year mining permit with a maximum annual production rate of 6 million tons. The mining would result in an open pit averaging 350 feet deep. The proposed reclamation plan for the Walltown Quarry project anticipates a lake in the mining pit as the end use, with a return to seasonal grazing on the other areas of the site. (Sacramento County 2007a:NOP-2.)

An NOP for the proposed Walltown Quarry project was prepared by Sacramento County and circulated for public review in December 2007. The requested entitlements for the Walltown project are the following: a General Plan Amendment and rezoning, a use permit to allow quarry mining and processing of materials, a reclamation plan, an encroachment permit, and a development agreement (Sacramento County 2007a:NOP-3). Potentially significant

environmental impacts associated with development of this site, as identified in the Walltown Quarry project NOP, include impacts on land use, traffic, air quality, drainage and hydrology, water quality, biological resources, noise, geology, aesthetics, and cultural resources.

DESILVA-GATES QUARRY

The proposed DeSilva-Gates Quarry site is located approximately 3.7 miles south of the SPA near the eastern Sacramento County line. Hard rock mining and reclamation would occur on approximately 480 acres within the 3,000-acre Barton Ranch property. Mining permits would allow for up to 6 million tons of rock aggregate production per year over 100 years (Sacramento County 2008c: NOP-3). The City and USACE understand that DeSilva-Gates recently withdrew its application for this project; however, in order to be conservative for purposes of this analysis, it is assumed that DeSilva-Gates quarry project will still go forward in the future with a different project applicant. Therefore, this quarry project is included in this cumulative analysis.

An NOP for the proposed DeSilva-Gates Quarry project was prepared by Sacramento County and circulated for public review in January 2008. The requested entitlements for the DeSilva-Gates Quarry project are the following: a General Plan amendment and rezoning, a use permit to allow quarry mining and processing of materials, a reclamation plan, an encroachment permit, and a development agreement (Sacramento County 2008c:NOP-3). Potentially significant environmental impacts associated with development of this site, as identified in the DeSilva-Gates Quarry project NOP, include impacts on land use, traffic, air quality, drainage and hydrology, water quality, biological resources, noise, geology, aesthetics, and cultural resources (Sacramento County 2008c:NOP-8). Although it is assumed that a different quarry project applicant will come forward in the future, it is reasonably forseeable that the same types of impacts identified in the NOP discussed above would occur regardless of which entity were operating the quarry project.

4.1.6 REGIONAL PLANNING ENVIRONMENT

Because the "Land" and "Water" portions of the project are influenced by regional development activities, the plan approach is also used to allow a cumulative analysis on this regional scale. The regional cumulative analysis area covers the incorporated and unincorporated areas of Sacramento County, western El Dorado County, the City of Folsom, the City of Rancho Cordova, and the Natomas Basin. This analysis includes an evaluation of the *Sacramento County General Plan* (Sacramento County 1993), *El Dorado County General Plan* (2004), the *City of Folsom General Plan* (1988), the City of Rancho Cordova General Plan (2006), the SACOG Sacramento Region Blueprint and Preferred Blueprint Scenario (SACOG and Valley Vision 2004b), Sacramento International Airport Master Plan, the Natomas Joint Vision Plan, and the Long-term CVP and SWP Operations Criteria Plan (OCAP). A summary of the cumulative planning environment in Sacramento County, El Dorado County, the Natomas Basin and the Cities of Folsom and Rancho Cordova that is used for the regional cumulative impact analysis is provided below.

SACRAMENTO COUNTY GENERAL PLAN

1993 Sacramento County General Plan

The Sacramento County General Plan provides for growth and development in the unincorporated area through 2010. Portions of the Sacramento County General Plan contain policies for urban development including urban communities and the infrastructure necessary to serve them. Other sections of the Sacramento County General Plan describe strategies to recognize and preserve areas of open space and natural resources. As a whole, the general plan reflects a balance between the amount and location of land uses in urban areas and those to remain in a rural or natural setting.

Community plans reflect the goals and policies of individual communities and guide land use and development of specific communities on a more detailed basis than the general plan. Sacramento County has adopted the

following community plans: Antelope, Arden-Arcade, Carmichael, Cordova, Delta, Fair Oaks, North Highlands/Foothill Farms, Orangevale, Rio Linda/Elverta, Southeast, South Sacramento, and Vineyard. Specific plans are detailed policy plans that identify allowable land uses and infrastructure needs for a specific geographic area and are most often used to comprehensively plan for development of new growth areas. Sacramento County has adopted the following specific plans: East Antelope, Elverta, Mather, and North Vineyard Station. (Sacramento County 2007b.)

In addition to community and specific plans, the Sacramento County General Plan identifies Commercial Corridor Plans that focus on planning for future improvements within specified commercial and transportation corridors on a more detailed basis than the general plan; Special Planning Areas that impose a "special" set of development standards for select areas that have unique qualities; and Neighborhood Preservation Areas, which are special zoning regulations that are adopted to preserve the unique qualities and characteristics of a neighborhood (Sacramento County 2007a).

The Sacramento County General Plan designates two boundaries that guide policies for growth within the county. The USB is the boundary of the urban area in the unincorporated County. It is a permanent boundary that will not be modified except under extraordinary circumstances and will be used as a planning tool for urban infrastructure providers for developing very long-range master plans that would accompany future urbanization. (Sacramento County 2009:3-11.)

The Urban Policy Area (UPA) defines the area expected to receive urban levels of public infrastructure and services within the 20-year planning period of the Sacramento County General Plan. The UPA provides the geographic basis for infrastructure master plans, particularly for public water and sewage, which require large capital investments and relatively long lead times for the installation of capital improvements. (Sacramento County 2009:3-11.)

SACRAMENTO COUNTY GENERAL PLAN UPDATE

The existing horizon of the Sacramento County General Plan ends in 2010, and the process to update the Sacramento County General Plan was initiated in 2002. In June 2007, Sacramento County prepared a draft general plan and began conducting an environmental review of the Sacramento County General Plan update. An NOP was prepared and circulated for public review in August 2007 (State Clearinghouse Number 2007082086). The DEIR for the general plan update was released on May 1, 2009, for a 45-day public review period. Adoption of the updated general plan is anticipated in mid 2010 (Sacramento County 2010).

The Sacramento County General Plan update will have a planning horizon of 2030, which is consistent with the planning horizons of SACOG's Sacramento Region Blueprint. The Sacramento County General Plan update contains objectives and policies that are intended to guide the County toward a more compact urban character by concentrating growth within existing urbanized areas and strategically located new growth areas, thereby using land resources as efficiently as possible (Sacramento County 2007b).

EL DORADO COUNTY GENERAL PLAN

The El Dorado County General Plan (2004) establishes a land use development pattern that makes the most efficient and feasible use of existing infrastructure and public services, defines those characteristics that make the County rural, provides guidelines for new and existing development that promotes a sense of community and maintains a rural quality of life, and provides opportunities for positive economic growth.

The general plan delineates areas where future higher density growth and urban/suburban-like activities are anticipated or will be directed. These areas may be defined as the expansion of existing communities within Community Regions and Rural Centers or the projected locations of Rural Regions and Planned Communities. The designations of Community Regions and Rural Center are applied to existing communities that contain the

highest concentration of high- and medium-density residential uses and commercial lands. Community Regions, which include Camino/Pollock Pines, El Dorado Hills, Cameron Park, El Dorado, Diamond Springs, Shingle Springs, and the City of Placerville, are existing larger communities that generally have well-developed infrastructure. Rural Centers are smaller communities, including Coloma, Cool, Georgetown, Grey's Corner, Grizzly Flat, Kelsey, Kyburz, Latrobe, Oak Hill, Phillips, Pilot Hill, Pleasant Valley, and Chrome Ridge, that provide limited services but are focal points for the surrounding rural areas. The designation of Rural Regions and Planned Communities is applied to the remaining unincorporated area and are identified as potential areas of future development. (El Dorado County 2004: 9.)

SUTTER COUNTY GENERAL PLAN

The Sutter County General Plan, adopted in 1996 and most recently amended on December 19, 2006, includes goals, objectives, and policies for the unincorporated areas of the county. The broad purpose of the Sutter County General Plan is to express policies that will guide decisions on future growth, development, and conservation of resources in a manner consistent with the goals and quality of life desired by the county's residents.

SUTTER COUNTY GENERAL PLAN UPDATE

In 2007, Sutter County began a work program to update the 1996 general plan. Thus far, the County has completed a number of public meetings related to the update. In February 2008, the County released the General Plan Update Technical Background Report (Sutter County 2008), which is available on the county's Web site. The technical background report includes an assessment of the current conditions, including the county's land use, economy, housing, and circulation systems. This information will be used as the basis for the development of the updated general plan, as well as preparation of the EIR for the plan. The County is currently preparing an EIR for the general plan update that is anticipated to be released for public review in 2010.

CITY OF FOLSOM GENERAL PLAN

The City General Plan provides for physical, economic, and environmental growth of the City. The City's General Plan is oriented toward the physical development of land uses, a circulation network, and supporting public facilities and services. As a whole, the general plan is intended to retain and enhance Folsom's quality of life, separate identity, and sense of community.

CITY OF RANCHO CORDOVA GENERAL PLAN

The City of Rancho Cordova General Plan serves as a compass to guide planners, the general public, and decision makers on the desired pattern of development in Rancho Cordova. It describes both existing and future land use activity, the latter of which was designed to achieve the city's long-range goals for physical development. The General Plan identifies the distribution, location, and intensity of all land use types throughout the city.

SACRAMENTO AREA COUNCIL OF GOVERNMENTS SACRAMENTO REGION BLUEPRINT

The SACOG Sacramento Region Blueprint depicts a way for the region to grow through the year 2050 as the current population of 2 million increases to more than 3.8 million, the number of jobs increases from 921,000 to 1.9 million, and the amount of housing increases from 713,000 to 1.5 million units (inclusive of the development described above). In December 2004 the SACOG Board of Directors adopted the Preferred Blueprint Scenario, a vision for growth that promotes compact, mixed-use development and more transit choices as an alternative to low-density development. The Preferred Blueprint Scenario predicts that undertaking a realistic long-term planning process will result in long-term environmental benefits and avoidance of impacts; these benefits are intended to minimize the extent of the inevitable physical expansion of the overall regional urban area. As a result, natural resources that might be lost under a traditional approach would be protected because less land would be required for urban uses and less agricultural land would be converted. In addition, the Preferred

Blueprint Scenario predicts less time per person devoted to travel, fewer car trips, and fewer miles traveled to work and local businesses. The reduction in traffic compared with what would occur under traditional patterns would lead to long-term reductions in air quality emissions in the region by reducing the amounts of vehicular carbon monoxide (CO) and particulate matter that would otherwise be emitted under traditional, lower density development patterns. (SACOG and Valley Vision 2004b.)

Although it is only advisory, the Blueprint provides policy guidance in the Sacramento region for long-term regional land use and transportation planning. A number of jurisdictions either are adopting the Blueprint concepts or are considering and encouraging projects consistent with the Blueprint. Although not establishing "buildout targets," the SACOG Blueprint Preferred Scenario anticipates an additional 24,400 households and 31,700 jobs in Folsom between 2000 and 2050 (SACOG and Valley Vision 2004c). With regard to the Folsom South of U.S. 50 Specific Plan project, the SACOG Blueprint Preferred Scenario anticipates approximately 12,000 households and 7,500 jobs would be generated by development of the SPA (City of Folsom 2007). The Blueprint assumes the city would have a population of 105,000 by 2050 and most of this growth would be located on vacant land within the current city boundaries and within the SPA. Further, the Blueprint anticipates the SPA would provide open space consistent with City policies and would be developed primarily with housing in similar amounts of detached and attached single-family units, rowhouses, townhomes, condominiums, and apartments to provide housing opportunities for the city's growing employment centers. (See Exhibit 3.10-2 in Section 3A.10, "Land Use and Agricultural Resources.").

SACRAMENTO INTERNATIONAL AIRPORT MASTER PLAN

The Sacramento International Airport Master Plan (Sacramento County Airport System 2007a) was adopted by the Sacramento County Board of Supervisors in August 2007. This plan represents the first full-scale master planning effort for the Airport since the mid-1970s. The master plan includes an evaluation of current conditions; definition of objectives, obstacles, and alternatives; an extensive public involvement program; and an implementation plan. The master plan is intended to guide airport development for at least the next 20 years. Phase 1 of the Master Plan (2007–2013) has been permitted and is under construction within the southern portions of "Zone 1" of the "Water" Study Area.

NATOMAS JOINT VISION PLAN

The Natomas Joint Vision Plan is a collaborative effort between the City and County of Sacramento to develop a vision for the area of the County known as Natomas. The Natomas Joint Vision Plan Project Area covers a contiguous land area of approximately 20,000 acres in the unincorporated northwestern area of Sacramento County, north of the city of Sacramento, and includes large sections of land within the south-eastern portion of NCMWC's service area. The joint vision strategy is grouped into five major phases, with Phase 1 complete, and Phase 2, outreach, currently in process. Phase 3 of the vision strategy will include a General Plan Amendment, and an amendment to City of Sacramento's Sphere of Influence. Phases 4 and 5 would consist of the eventual annexation and development of the vision area. Although the Natomas Joint Vision is not a specific development proposal, but rather would consist of numerous individual development projects, this planning process is integral to future development within the Natomas Basin and, therefore, the City considered this planning process as part of its cumulative analysis for Zone 1 of the "Water" Study Area.

An EIR is currently in preparation for use by the City, County, and LAFCo in their evaluation of the effects of the City of Sacramento's SOI amendment and necessary text and map amendments to both the City of Sacramento and Sacramento County General Plans. The EIR is being prepared jointly by LAFCo and the City of Sacramento as co-lead agencies with the County participating as a responsible agency. The draft EIR has been delayed pending the development of a more precise project description.

LONG-TERM CENTRAL VALLEY PROJECT AND STATE WATER PROJECT OPERATIONS CRITERIA AND PLAN

The CVP/SWP OCAP consists of the continued operation of the CVP and SWP and includes the operation of the temporary barriers project in the south Delta and the 500 cubic feet per second increase in SWP Delta export limit July through September. In addition to current day operations, several other actions are included in the OCAP and the supporting Biological Opinion (BO) issued by the National Marine Fisheries Service (NMFS) as part of the Section 7, Federal Endangered Species Act consultation. These actions include the following improvements: (1) an intertie between the California Aqueduct and the Delta-Mendota Canal (DMC); (2) the operation of permanent gates, which will replace the temporary barriers in the South Delta; (3) changes in the operation of the Red Bluff Diversion Dam (RBDD); and (4) Alternative Intake Project for the Contra Costa Water District.

According to the OCAP, the CVP has 253 water service contracts (including Sacramento River Settlement Contracts). These water service contracts have had varying water shortage provisions (e.g., in some contracts, M&I and agricultural uses have shared shortages equally; in most of the larger M&I contracts, agricultural water has been shorted 25% of its contract entitlement before M&I water was shorted, after which both shared shortages equally).

Lastly, the OCAP assumes that annual demands on the American and Sacramento Rivers are estimated to increase from about 324,000 AF in 2005 and 605,000 AF in 2030 without the Freeport Project maximum of 133,000 AF during drier years. In addition, the OCAP accounts for Reclamation's ongoing negotiations relating to the renewal of 13 long-term water service contracts, four Warren Act contracts, and has a role in six infrastructure or Folsom Reservoir operations actions influencing the management of American River Division facilities and water use for local water purveyors including the City, Placer County Water Agency, EID, San Juan Water District, and the Carmichael Water District.

4.1.7 ANALYSIS OF CUMULATIVE IMPACTS

The following sections discuss the cumulative effects anticipated from implementation of the "Land" and "Water" portions of the Folsom South of U.S. 50 Specific Plan project, together with the related projects and regional development, for each of the 16 environmental issue areas evaluated in this EIR/EIS. The analysis conforms with CCR Section 15130 of the State CEQA Guidelines, which specifies that the "discussion of cumulative impacts shall reflect the severity of the impacts and their likelihood of occurrence, but the discussion need not provide as great a detail as is provided of the effects attributable to the project alone." The Council on Environmental Quality (1997) provides for a similar approach.

AESTHETICS

The visual character of the SPA and Off-site Water Facilities Study Area is characterized by sweeping view of the Central Valley, coupled with the oak woodlands and grass-covered hillsides. This region is part of the Sierra Nevada foothills and the Central Valley, and is exemplary of those landscapes and of resources that are endemic to the area. Nearby planned or approved developments include the Westborough at Easton Specific Plan project to the west; the Promontory, El Dorado Hills, and Bass Lake Specific Plans projects to the northeast; the Valley View Specific Plan project to the east; and the Carson Creek Specific Plan project to the southeast. These projects would substantially change the visual conditions as open viewsheds are replaced by urban development.

At full buildout, the SPA would consist of developed urban land uses with small areas of open space and parks. Implementation of the "Land" portion of the project would substantially degrade this scenic vista, damage the character of the viewshed from a Sacramento County-designated scenic corridor, and alter the visual character of the SPA. Views along nearby roadways, including Scott Road, Old Placerville Road, White Rock Road, Prairie City Road, and U.S. 50, would change to urban land uses. Furthermore, viewsheds that include the SPA are part of thousands of acres of open space that would no longer exist. This area would become of similar visual quality

to nearby developed land, and would no longer be considered a unique or scenic vista. Therefore, the "Land" portion of the project would permanently and substantially alter the scenic vista in the SPA. No feasible mitigation measures are available to reduce impacts associated with the alteration of scenic vistas from project development to a less-than-significant level because project development would result in a permanent, large-scale change.

Although the SPA does not contain, nor is it visible from, a state-designated scenic highway, Scott Road south of White Rock Road is a designated scenic corridor in Sacramento County. The Scenic Highways Element of the Sacramento County General Plan describes views from this roadway to consist of grasslands and cattle-grazing lands. These views are exemplary of rural Sacramento County landscape. Implementation of the "Land" portion of the project would substantially damage views from the portion of Scott Road designated as a scenic corridor through conversion of the existing grassland and cattle grazing land to urban development and the site would no longer provide exemplary views of rural Sacramento County landscape. No feasible mitigation measures are available to reduce impacts associated with the damage of scenic resources within a County-designated scenic corridor to a less-than-significant level.

Nearby planned or approved developments and other development in the project region as a whole would substantially change visual conditions as open viewsheds are replaced by urban development. Increased urban development would also lead to increased nighttime light and glare in the region and more limited views of the night sky and sky glow effects. Views of the SPA and the alternative WTP sites contribute to this change in regional visual conditions, since the SPA and alternative WTP sites would be permanently altered to urban development, substantially degrading viewsheds located on Scott Road, Old Placerville Road, Prairie City Road, White Rock Road, U.S. 50, and for people located within the community of El Dorado Hills, the City of Folsom, the City of Rancho Cordova, and nearby rural residences. After development of the SPA under the "Land" portion of the project and booster pump station and WTP alternatives under the "Water" portion of the project, visual conditions in the SPA, booster pump station, and the WTP alternatives would be similar to existing views of urban settings found elsewhere in the project region. The "Land" and "Water" portions of the project include standards for design, architecture, development, and maintenance thereby ensuring that the general visual quality and character of development under the "Land" and "Water" portions of the project would be consistent with viewer expectations for similar urban environments; however, this would only partially reduce the impacts of degradation of visual character. The effect of these changes, when considering the related projects, on aesthetic resources from past and planned future projects is a cumulatively significant impact.

Assessment of visual quality is a subjective matter and reasonable people may differ as to the aesthetic value of undeveloped grasslands and oak woodlands, and whether development of urban uses in the plan area would constitute a substantial degradation of the existing visual character or quality of the site and its surroundings. Given the large scale of this urban development and the rural nature of its setting, the impacts on visual resources from implementation of the "Land" portion of the project are significant. Although design, architectural, development, and lighting standards are included to ensure that urban development in the plan area and region remains within certain aesthetic guidelines, there is no mechanism to allow implementation of the "Land" portion of the project and the related projects while avoiding the conversion of open space to urban development. Therefore, the change of views in the project region to urban land uses and the associated increase in nighttime light and glare are cumulatively significant and unavoidable impacts. In addition, the incremental contribution of the "Land" portion of the project to these impacts is cumulatively considerable (i.e., significant in and of itself).

Adoption of the Folsom General Plan Amendment (proposed GPA) would result in construction of additional multifamily residential units on infill parcels within the built-up area of the City of Folsom. These urban uses would occur in an infill area already characterized by similar uses. Therefore, the proposed GPA would not contribute to cumulatively considerable visual character or scenic view impacts. However, construction of the additional units under the proposed GPA could considerably contribute to cumulatively significant light and glare impacts.

AIR QUALITY

Both the "Land" and "Water" portions of the project are located in the Sacramento Valley Air Basin (SVAB). Past development in the SVAB combined with meteorological conditions has resulted in significant cumulative impacts on air quality. As described in Sections 3A.2 and 3B.2, "Air Quality," the SVAB is in nonattainment status for ozone and respirable particulate matter with an aerodynamic diameter of 10 micrometers or less (PM_{10}). The air quality impacts of the proposed GPA are included in the analysis of the "Land" portion of the project.

At the local level, the SPA and the Off-site Water Facilities Study Area are located in the jurisdiction of the Sacramento Metropolitan Air Quality Management District (SMAQMD). Under the "Land" portion of the project, all of the off-site elements of the project would also be under the jurisdiction of SMAQMD except the two roadway extensions into El Dorado County, which would be under the jurisdiction of the El Dorado County Air Quality Management District (EDCAQMD).

Temporary, Short-Term Construction Impacts

The "Land" and "Water" portions of the project would result in significant and unavoidable temporary, short-term construction-related air quality impacts even with implementation of all feasible mitigation measures identified in Sections 3A.2 and 3B.2, "Air Quality." Project-generated construction-related emissions would exceed SMAQMD's significance threshold of 85 pounds per day (lb/day) for oxides of nitrogen (NO_X), and substantially contribute to emissions concentrations that exceed the National Ambient Air Quality Standards (NAAQS) and the California Ambient Air Quality Standards (CAAQS) for ozone and PM_{10}. The projected total maximum daily construction emissions for some of the off-site elements would also individually exceed SMAQMD's significance threshold of 85 lb/day for NO_X, and substantially contribute to emissions concentrations that exceed the NAAQS and CAAQS for ozone and PM_{10}.

Assuming that all related projects would also implement all feasible construction emission control measures consistent with respective SMAQMD and EDCAQMD guidelines, construction emissions on some of the related projects may be less than significant, although it is likely that larger projects, such as the Easton and Cordova Hills developments, and other projects identified in Table 4-2, would result in significant and unavoidable air quality impacts on their own. This impact cannot be more precisely determined because the related projects would develop on their own schedules, some of which are not known. It would, thus, be speculative to try to add together the various projects with their differing and changing schedules. However, given the large scale of development that would occur with the related projects, taken in total and combined with the nonattainment status of the SVAB for ozone and PM_{10} and other development that would occur in the SVAB, these cumulative projects would result in a cumulatively considerable construction-related air quality impact. Because implementation of the "Land" and "Water" portions of the project would result in a significant and unavoidable impact from the generation of NO_X, and PM_{10}, the "Land" and "Water" portions of the project would result in a cumulatively considerable incremental contribution to a significant cumulative impact.

Long-Term Operational Impacts

Operation-related activities of the "Land" portion of the project would result in project-generated mass emissions of NO_X that exceed SMAQMD's significance threshold of 65 lb/day. Implementation of mitigation measures contained in Section 3A.2, "Air Quality," would reduce impacts associated with emissions of NO_X, but not to less-than-significant levels. Operation-related activities of the "Water" portion of the project would not result in mass emissions of NO_X that exceed SMAQMD's significance threshold. Related projects would similarly contribute to a degree and their relative level of contribution is generally related to their size. Long-term operational emissions from related projects, considered in light of the nonattainment status of the air basin, would be cumulatively significant. Emissions attributable to the project, plus cumulative development listed on Table 4-2, and emissions from other reasonably foreseeable future projects in SVAB as a whole, would continue to contribute to long-term increases in emissions that would exacerbate existing and projected nonattainment

conditions. Thus, the project would result in a cumulatively considerable incremental contribution to a significant cumulative long-term operational air quality impact.

Toxic Air Contaminants

The "Land" and "Water" project activities related to temporary, short-term construction and long-term operations, could expose nearby existing off-site or proposed on-site sensitive receptors to toxic air contaminant (TAC) emissions. TAC emissions associated with temporary, short-term construction activities and stationary sources are site-specific and would be potentially significant for the "Land" and "Water" portions of the project. The proposed on-site commercial and industrial land uses have not yet been identified and could potentially generate substantial volumes of truck activity (e.g., warehouses, distribution centers) that could potentially be in the proximity of nearby sensitive receptors, thereby exposing these nearby on-site receptors to mobile-source TACs. Under the "Land" portion of the project, related impacts associated with on-site mobile source TACs are significant and unavoidable even with implementation of mitigation measures identified in Section A3.2, "Air Quality." Under the "Water" portion of the project, operational emissions associated with the booster pump station and White Rock WTP or Folsom Boulevard WTP facilities could expose sensitive receptors TACs. However, with mitigation, the project would not result in a cumulatively considerable contribution to a significant cumulative impact related to regional mobile source TACs.

Under the "Land" portion of the project, project-related exposure to mobile-source TAC emissions from nearby U.S. 50 and other high traffic-volume roadways are significant and unavoidable, with or without additional quarry truck trips in the local roadway network, and despite implementation of all feasible mitigation measures identified in Section A3.2, "Air Quality." Related projects would also develop land uses that would substantially increase traffic on nearby freeways and subsequently increase emissions of off-site mobile-source TACs. Given the large scale of development that would occur with the related projects, taken in total and combined with the increase in traffic-related pollutant emissions from U.S. 50 and other high traffic-volume roadways, the related projects would result in significant and unavoidable cumulative mobile-source TAC impacts. Therefore, the "Land" portion of the project would result in a cumulatively considerable incremental contribution to a significant cumulative TAC impact related to mobile-source TAC emissions from nearby U.S. 50 and other high traffic-volume roadways. See below for a detailed evaluation of the potential exposure of sensitive receptors in the SPA to TACs generated by quarry truck trips.

Land Use Compatibility with High-Volume Arterial Roadways

According to the land use planning maps for the Proposed Project and the other four "Land" action alternatives (see Chapter 2, "Alternatives"), arterial roadways that carry high volumes of traffic would pass by schools and residential land uses in the SPA. These roadways include segments of Prairie City Road, Oak Avenue, Scott Road, and White Rock Road. These roadways are of particular concern because they may accommodate a disproportionately high volume of diesel-powered truck trips, most of which would be associated with operation of the Teichert Quarry and other sand and gravel quarries south of the SPA. According to the *Draft EIR for the Teichert Quarry General Plan Amendment, Rezone, Use Permit, Reclamation Plan and Development Agreement* (County of Sacramento Department of Environmental Review and Assessment 2008), quarry trucks would travel by or through the SPA to U.S. 50 en route to their final destinations. The Draft EIR for the Teichert Quarry project does acknowledge the development of the SPA, it does not fully analyze the potential impacts of TAC-emitting truck traffic at off-site sensitive receptors, including those planned in the SPA. According to SMAQMD staff, the proportion of diesel trucks on the roadways is important because the volume of diesel trucks is the key variable used to develop the screening levels in SMAQMD's Protocol (DuBose, pers. comm., 2009). In order to understand the effect of the quarry truck traffic on roadways that pass by sensitive receptors, which was not addressed in any previous environmental documentation, the analysis prepared for the Folsom South of U.S. 50 Specific Plan analyzed the TAC impact of projected future travel volumes both with and without additional truck traffic from the nearby quarries. As part of this analysis, an adjustment factor was incorporated to account for the fact that traffic on arterial roadways would travel at lower speeds—and thus have different emission rates—than traffic flowing at typical freeway speeds. In addition, this analysis also examined the projected traffic volumes

using emission rates for the vehicle fleet under existing conditions (year 2010) as well as emission rates projected for the year 2030, when full build out of the project would be completed. According to model runs performed in ARB's Motor Vehicle Emissions Inventory Model (EMFAC2007) (ARB 2006), emission rates from heavy, diesel-powered trucks are expected to be substantially lower in 2030 than 2010. This reflects the fact that emission factors in future years are expected to be lower than current levels because of more stringent vehicle emissions standards, improvements in vehicle emissions technology, and statewide efforts to replace older diesel engines with new or retrofitted, cleaner engines. It is important to consider the emission factors of both the existing and future vehicle fleets in order to understand what the risk levels would be during intermediate years because there is the potential that the daily traffic volumes on roadways would increase considerably before full build out while the emission rates of the vehicle fleet during a particular intermediate year are still relatively high.

Thus, for each road segment that would pass by locations where on-site sensitive receptors would be developed in the SPA, a separate analysis was conducted with and without the additional quarry truck traffic and with existing and future projected emission rates (i.e., for vehicle fleets in 2010 and 2030. The results of the analysis are summarized in Table 4-4. All detailed calculations and assumptions are provided in Appendix C1.

As shown in Table 4-4, all direct impacts associated with TAC exposure levels at receptors along all roadway segments studied for this analysis would be less than significant without the addition of quarry truck trips. No indirect impacts would occur.

However, when quarry truck trips are added to modeled roadway segments before the year 2030, traffic volumes within 400 feet of sensitive receptors that would be constructed in the SPA could result in exposure of those receptors to high levels of toxic air contaminants (see Table 4-4). Therefore, this direct impact would be potentially significant. No indirect impacts would occur.

As discussed above, it is reasonably forseeable that the quarry truck vehicle fleet that would be used from the year 2030 onward would have lower emission factors as compared to current levels because of more stringent vehicle emissions standards, improvements in vehicle emissions technology, and statewide efforts to replace older diesel engines with new or retrofitted, cleaner engines. Therefore, as shown in Table 4-4, modeling results indicate that all direct impacts associated with TAC exposure levels at receptors along all roadway segments studied for this analysis would be less than significant with the addition of quarry truck trips after the year 2030.

Cumulative Mitigation Measure AIR-1-Land: Implement Measures to Reduce Exposure of Sensitive Receptors to Operational Emissions of Toxic Air Contaminants from Quarry Truck Traffic.

The City of Folsom does not have direct jurisdiction over the Teichert, DeSilva Gates, or Walltown quarry project applicants as these projects are located within the unincorporated portion of the County of Sacramento. The City's authority to control the activities of the quarry trucks includes restrictions or actions that would be applicable within the City's jurisdictional boundaries. For example, the City could designate truck routes through the City consistent with California Vehicle Code section 21101(c), including truck routes in the Folsom South of U.S. 50 project area, so as to prohibit or limit quarry trucks' use of City roads adjacent to areas where projected truck traffic volumes would otherwise result in exposure of sensitive receptors to operational emissions of toxic air contaminants from quarry truck traffic and/or traffic safety hazards. If this approach is selected by the City, then prior to the approval of the first tentative subdivision map or any other discretionary project approval that would place sensitive receptors along any roads the quarry trucks could use to access U.S. 50, the City's traffic department and consultants shall analyze and propose to the City Council for approval designated truck routes from the quarries through City jurisdiction to access U.S. 50 that would allow a level of truck traffic that would avoid any potentially significant impact on sensitive receptors from toxic air contaminant emissions within the Folsom South of U.S. 50 project area, as well as any other existing or planned uses that would contain sensitive receptors, so as to ensure that the risk of cancer to sensitive receptors is no more than 296 in one million (or such different threshold of significance recommended by SMAQMD or ARB at the time, if any) as may be determined by a Health Risk Assessment (HRA) paid for by the applicant.

As an alternative to designating truck routes, the following measures could be voluntarily implemented by the quarry project applicant(s) (Teichert, DeSilva Gates, and Granite [Walltown]) to reduce exposure of sensitive receptors to TACs generated by quarry truck traffic and are encouraged:

- The quarry project applicant(s) should meet with the City of Folsom to discuss mitigation strategies, implementation, and cost.

- A site-specific, project-level screening analysis and/or Health Risk Assessment (HRA) should be conducted by the City of Folsom and funded by the quarry truck applicant(s) for all proposed sensitive receptors (e.g., residences, schools) in the SPA that would be located along the sides of roadway segments that are identified in Table 4-4 as being potentially significant under any of the analyzed scenarios. Each project-level analysis shall be performed according to the standards set forth by SMAQMD for the purpose of disclosure to the public and decision makers. The project-level analysis shall account for the location of the receptors relative to the roadway, their distance from the roadway, the projected future traffic volume for the year 2030 (including the proportion of diesel trucks), and emission rates representative of the vehicle fleet for the year when the sensitive land uses would first become operational and/or occupied. If the incremental increase in cancer risk determined by in the HRA exceeds 296 in one million (or a different threshold of significance recommended by SMAQMD or ARB at the time, if any), then project design mitigation should be employed, which may include the following:

    - Increase the setback distance between the roadway and affected receptor. If this mitigation measure is determined by the City of Folsom to be necessary, based on the results of the HRA, the quarry truck applicant(s) should pay the Folsom South of 50 Specific Plan project applicant(s) and the City of Folsom a fee that shall serve as compensation for lost development profit and lost City tax revenues, all as determined by the parties. Said mitigation fee shall be determined in consultation with the quarry project applicant(s), the Folsom South of 50 Specific Plan project applicant(s), and the City of Folsom. No quarry trucks shall be allowed to pass on any roadway segment immediately adjacent to or within the SPA until said mitigation fees are paid.

    - Implement tiered tree planting of fine-needle species, such as redwood, along the near side of the roadway segments and, if feasible, along the roadway 500 feet in both directions of the initial planting (e.g., 500 feet north and south of a roadway that runs east-west) to enhance the dispersion and filtration of mobile-source TACs associated with the adjacent roadway. These trees should be planted at a density such that a solid visual buffer is achieved after the trees reach maturity, which breaks the line of sight between U.S. 50 and the proposed homes. These trees should be planted before occupation of any affected sensitive land uses. This measure encourages the planting of these trees in advance of the construction of potentially affected receptors to allow the trees to become established and progress toward maturity. The life of these trees should be maintained through the duration of the quarry projects. The planting, cost, and ongoing maintenance of these trees should be funded by the quarry project applicant(s).

    - To improve the indoor air quality at affected receptors, implement the following measures before the occupancy of the affected residences and schools:

        – equip all affected residences and school buildings developed in the SPA with High Efficiency Particle Arresting (HEPA) filter systems at all mechanical air intake points to the interior rooms;

        – use the heating, ventilation, and air conditioning (HVAC) systems to maintain all residential units under positive pressure at all times;

– locate air intake systems for HVAC as far away from roadway air pollution sources as possible; and

– Develop and implement an ongoing education and maintenance plan about the filtration systems associated with HVAC for residences and schools.

To the extent this indoor air quality mitigation would not already be implemented as part of the Folsom South of 50 Specific Plan project development, this mitigation should be paid for by the quarry project applicant(s) before any quarry trucks are allowed to pass on any roadway that is within 400 feet of any residence or school within the SPA.

Implementation: The project applicant(s) of the Folsom South of 50 Specific Plan project.

Timing: Prior to approval of first tentative map or discretionary approval within SPA that would place sensitive receptors along roadways that quarry trucks would reasonably use to access U.S. Highway 50.

Enforcement: City of Folsom Community Development Department.

Implementation of Cumulative Mitigation Measure AIR-1-Land would reduce the significant impact related to exposure of project-generated sensitive receptors to toxic air contaminants generated by quarry truck trips to a less-than-significant level because the City would either designate truck routes that would limit or prohibit truck traffic adjacent to sensitive receptors or the City would be able to reach a voluntary agreement with the quarry applicants that would require a site-specific health risk assessment to be performed according to SMAQMD protocol, and in the event the cancer risk would exceed 296 in one million, or whatever threshold of significance is recommended by SMAQMD at the time, either the setback distances of the sensitive receptors from the road would be increased, or fewer quarry trucks would be allowed to pass on the roadways within 400 feet of the sensitive receptors. However, because the City of Folsom does not have jurisdiction over the Teichert, DeSilva Gates, or Walltown quarry project applicants and operations, if the quarry project applicants decline to voluntarily implement the recommended mitigation, the City may adopt truck route restrictions, thereby reducing the impact to a less-than-significant level.

Carbon Monoxide

As described in Sections 3A.2 and 3B.2, “Air Quality,” implementation of the “Land” and “Water” portions of the project would result in less-than-significant local mobile source CO–related air quality impacts. CO emission factors in future years are expected to be lower than current levels due to more stringent vehicle emissions standards and improvements in vehicle emissions technology. Thus, ambient local CO concentrations under cumulative conditions would continue to decline. Therefore, 1- and 8-hour CO concentrations for the future cumulative conditions would not be anticipated to exceed the significance thresholds of 20 parts per million (ppm) and 9 ppm, respectively. Consequently, the “Land” and “Water” portions of the project would not result in a cumulatively considerable incremental contribution to a significant cumulative impact related to increases in traffic volumes on the local roadway network relative to CO concentrations.

Odor Emissions

Odor intensity is a subjective measurement that is perceived differently depending on individual sensitivity. Depending on prevailing wind directions and speeds, odors may be limited to a small area immediately surrounding the source, or may be carried for longer distances to land uses further from the source. Most of the related projects considered in this analysis would result in the generation of odors on a short-term basis from construction activities, and on a long-term basis from operational activities.

Notes: PS = potentially significant; LTS = less than significant
Source: Data compiled by AECOM 2010.

Operation-related activities at the proposed on-site industrial and commercial areas could result in project-generated emissions of odors. Specific uses within those designations are not yet known and detailed site and grading plans have not yet been developed; however, these types of uses could entail painting/coating operations (e.g., auto body shops) and fast food restaurants in close proximity to proposed sensitive receptors. Thus, project-generated, on-site operation-related sources could directly expose existing and proposed receptors to emissions of objectionable odors. Implementation of mitigation measures identified in Section A3.2, "Air Quality," would reduce the exposure of sensitive receptors under the "Land" portion of the project to project-generated odor emissions to a less-than-significant level. Operation-related activities of the "Water" portion of the project could result in project-generated emissions of odors from operation of the White Rock WTP or Folsom Boulevard WTP. However, treatment chemicals used in the water treatment processes would be stored in an enclosed building and would not generate odors off-site.

New residents that would be generated by the Eason project immediately west of the "Land" portion of the project could be exposed to odors associated with construction and operation of the project. In addition, new residents that would be generated within the SPA could be exposed to odors generated by the Easton project to the west, by the proposed City Corporation Yard to the south, and by the proposed Sacramento GreenCycle Project further south below the corporation yard. Therefore, the project's odor impacts, when considered in combination with odor impacts of the related projects, could result in cumulatively significant impacts.

BIOLOGICAL RESOURCES

In addition to the related projects considered for all resource areas in this EIR/EIS, the projects identified in Table 4-5 below are also considered in the cumulative analysis for biological resources because the USACE has specifically requested an additional level of detailed cumulative analysis related to biological resources that includes a variety of additional projects to determine cumulative impacts on wetlands and waters of the U.S.

With regards to cumulative impacts related to the proposed GPA, the GPA would change permitted densities, but would not change the physical locations identified for Single Family, Multi-family Medium Density, and Multi-family High Density development in the existing Folsom General Plan. Therefore, for issue areas such as biological resources, which are related to land coverage, there would be change from the analysis already contained in the City's existing General Plan.

Generally, the geographic extent of cumulative impacts on wetlands (e.g., vernal pools, seasonal wetland swales, seeps) and other waters of the U.S. (e.g., perennial and intermittent drainage channels), oak woodlands, and biological resources associated with these habitats includes the vernal pool and blue oak woodland regions of El Dorado County, Sacramento County, and neighboring counties that support similar biological resource values and functions to those of the SPA.

Many projects near the SPA and the Off-Site Water Facilities have been constructed recently or are in various stages of planning and entitlement. Some have already resulted in adverse impacts on wetlands and other waters of the U.S. Tables 4-2 and 4-3 summarize the impacts on water of the United States of the surrounding projects that were considered in the cumulative biological resources impact analysis for the "Land" and "Water" portions of the project.

As indicated in Table 4-5, based on the data currently available, cumulative losses of wetlands and other waters of the U.S., including vernal pools, for specific projects within surrounding areas of Sacramento and El Dorado Counties in the same watershed and supporting similar biological resources have been and are expected to be substantial. Thus, related projects throughout the region would result in a cumulatively significant impact to wetlands and these habitats. Due to its size and large acreage of habitats that would be lost as a result of implementation of the "Land" portion of the project, the "Land" portion of the project would contribute substantially to this regional loss. In addition, because the exact placement of the Folsom Boulevard WTP and

conveyance pipeline alternative alignments has not been determined, the "Water" portion of the project could further contribute substantially to this regional loss.

Implementing the Folsom South of U.S. 50 Specific Plan project would result in a cumulatively considerable incremental contribution to the regional loss of the habitat types presented in Table 4-6. Each of these habitats has the potential to support special-status species, as listed in Table 4-6. Therefore, project implementation would result in a cumulatively considerable incremental contribution to the decline of these species in the region.

Table 4-6
Special-Status Species Supported By the Habitat Types to Which the Project Would Contribute a Cumulatively Considerable Incremental Loss

Habitat Type	Special-Status Species Supported
Vernal Pools, Seasonal Wetlands, and Swales	Dwarf downingia
	Tuolumne button-celery
	Bogg's Lake hedge-hyssop
	Ahart's dwarf rush
	Greene's legenere
	Pincushion navarretia
	Slender Orcutt grass
	Sacramento Orcutt grass
	Vernal pool fairy shrimp
	Vernal pool tadpole shrimp
	Western spadefoot toad
	Northwestern pond turtle
Annual Grassland	Swainson's hawk
	White-tailed kite
	Tricolored blackbird
	Grasshopper sparrow
	Burrowing owl
	Northern harrier
	Loggerhead shrike
	American badger
Oak Woodland	Brandegee's clarkia
	Swainson's hawk
	White-tailed kite
	American badger

Source: Data provided by AECOM in 2010

The "Land" and "Water" portions of the project would result in degradation of wildlife habitat by developing new facilities that, when combined with other habitat impacts occurring from development within the region, would result in significant cumulative impacts. Despite the implementation of project-specific measures identified in Sections 3A.3 and 3B.3 "Biological Resources," to mitigate impacts on biological resources, a temporal loss of wetlands and other waters of the U.S. and blue oak woodland would occur during implementation of mitigation until performance standards and success criteria are met. Within the SPA, 84.94 acres of aquatic habitat exists, including vernal pools and other seasonal wetlands, seeps, ponds, and stream channels. Of these, 40.75 acres

(45%) would be permanently destroyed by project implementation. A total 50.7 acres of aquatic habitat occurs within all of Zone 4 of the "Water" Study Area and up to 13.5-acres of this total area could potentially be impacted by one or more of the Off-site Water Facility Alternatives. Off this total, approximately 45.9 acres reside within the Morrison Creek Watershed, while the remaining 4.8-acres occurring with the Coon-American sub-watershed.

It is estimated that 75% to 90% of the historic California vernal pool habitat has been lost. Results of surveys of vernal pool distribution in the Central Valley indicate that 13% of the 1,032,853 acres of vernal pool habitat mapped in 1997 was gone by 2005 (Placer Land Trust 2008). Losses of vernal pool habitat in the project region in that time period were substantial, with Sacramento County losing approximately 6,550 acres and El Dorado County losing approximately 260 acres. In the period between 1994 and 2005, Placer County lost approximately 17,115 acres of vernal pool habitat (Placer Land Trust 2008). In Sacramento County, two large new growth areas—Jackson Highway New Growth Area and Grant Line East New Growth Area—are planned for major urbanization between now and 2030. These two new growth areas support a combined 316 wetted acres of vernal pools that could be converted to urban land uses by the year 2030 (Sacramento County 2009). Full buildout of the City of Rancho Cordova General Plan planning area is projected to convert up to 20,728 acres of vernal pool grasslands containing 630 wetted acres of vernal pools. Historic losses of vernal pool habitat in combination with projected losses from existing, proposed, planned, and approved projects constitute a cumulatively substantial reduction in vernal pool habitat in the region. Habitat losses of this magnitude have a substantial adverse effect on species that rely on this habitat type, including Federally-listed vernal pool crustaceans, and contribute to the decline of these species.

The "Land" portion of the project would fill approximately 24.42 acres of vernal pools, seasonal wetlands, and seasonal wetland swales and would contribute to a cumulative loss of these wetland habitats in the region. Additional aquatic habitats that would be filled consist of 4.48 acres of seeps, 0.07 acre of marsh, 0.11 acre of willow scrub, 10.42 acres of other waters of the U.S. (i.e., ponds, stream channels, and ditches), and 1.25 acres of other aquatic habitats that are not waters of the U.S. (i.e., isolated waters). In addition, the project, when combined with surrounding planned projects, would result in the conversion of large, open habitat landscapes surrounded by other open space to smaller patches of habitat surrounded by urban development. Therefore, aquatic habitats would be confined to small geographic locations and would be more vulnerable to the effect of habitat fragmentation and other indirect impacts.

Implementation of the "Water" portion of the project could result in the fill of additional vernal pools through construction of the WTP alternatives and the conveyance pipeline alternative alignments. Portions of the Zone 4 of the "Water" Study Area within the Morrison Creek watershed include 10.3 acres of vernal pool habitat, 5.8 seasonal wetland, and 0.4 acres of seasonal wetland swale, of which the Off-site Water Facility Alternatives could impact up to 3.4 acres of vernal pools, 2.3-acres of seasonal wetland, and 1.6 acres of seasonal wetland swale within the Morrison Creek watershed. Impacts to these aquatic features as part of the Off-site Water Facility Alternatives would result in impacts to up to 2.9% of vernal pools, 3.8% of seasonal wetlands, and 2.2% of seasonal wetland swales as mapped within the Morrison Creek Watershed. Although, only a small portion of Zone 4 of the "Water" Study Area lies within the Coon-American Watershed, given only limited aquatic resources exist, the corresponding proportion of potential impacts would be greater with 18% of vernal pools, 17.6% seasonal wetlands, and 23.5% of the seasonal wetland swales potentially impacted. These impacts when considered along with the quantity of wetlands and other waters present in the new growth areas of Sacramento County, including Jackson Highway, East of Grant Line Road, and Easton, which are expected to be converted to urban land uses by the year 2030, impacts to wetlands are cumulatively considerable (Sacramento County 2009).

Considering the rate of development in Sacramento County and the limited amount of undeveloped, unspoken for land that supports existing wetlands that could be preserved, or that is suitable for creation of compensatory aquatic habitats similar to those that would be removed by implementation of the "Land" portion of the project, it may not be possible to fully mitigate the loss of habitat functions and values provided by the nearly 41 acres of aquatic habitats that would be lost in the SPA.

Blue oak woodland habitat is rapidly declining in the Sacramento Valley and Sierra Nevada foothill region and a large percentage of previously existing blue oak woodland has already been lost from the region. It is estimated that more than a million acres of California's oak woodlands were lost between 1950 and 1988 (Bolsinger 1988) and another 750,000 acres are at risk of being converted to urban land uses by 2040 (California Oaks Foundation 2006: 6). Some of the largest losses of oak woodland habitat have occurred in areas surrounding or near the SPA in El Dorado and Placer Counties. It is projected that nearly 300,000 acres of oak woodlands could be developed in the Sacramento region by 2040 and the largest anticipated losses of oak woodland in the state are in El Dorado County, which is projected to lose 80% of its oak woodlands by 2040 (California Oaks Foundation 2006: 15). Over half of the existing oak woodlands in Placer, Nevada, and Yuba Counties are at risk of development by 2040 (California Oaks Foundation 2006: 15). Sacramento County supports just over 8,000 acres of oak woodland habitat, 7,250 of which are blue oak woodland. The SPA contains a relatively large percentage (13%) of the county's blue oak woodland habitat with approximately 949 acres. Although the project has been designed to preserve the majority of oak woodland habitat in the SPA, approximately 47% (444 acres) of the existing blue oak woodland community would still be removed. This constitutes a significant contribution to the regional loss of this biological resource, which provides important functions and values to common and special-status plant and animal species and functions in carbon sequestration, and therefore results in a significant contribution to a cumulatively considerable impact.

The "Land" portion of the project would result in the loss of 2,219 acres of annual grassland habitat, which serves as foraging habitat for raptors, including Swainson's hawk, and other grassland associated wildlife species, and nesting habitat for burrowing owl. This loss would contribute significantly to the cumulatively considerable regional loss of this biological resource.

As indicated in Section 3B.3, "Biological Resources - Water," the conveyance pipeline alternative alignments would generally be constructed within existing road rights-of-way and disturbed grasslands, thereby generally minimizing disturbance to sensitive habitats and areas that potentially support special-status species bordering the roadway road rights-of-way. However, it is difficult to predict with certainty the exact placement of the conveyance pipeline within the roadway for each alternative. Based on the use of a 100-foot-wide construction easement, the conveyance pipeline could directly or indirectly affect several Federal and state-listed species that use adjacent seasonal wetlands, vernal pool complexes, annual grasslands, oak savanna, and riparian and other aquatic communities within Zone 4 of the "Water" Facilities Study Area. Without mitigation, construction-related impacts combined with other land development and roadway improvement projects within the conveyance pipeline alternative alignments could be cumulatively considerable.

Implementation of mitigation measures in Section 3A.3, "Biological Resources - Land," would reduce the direct project-specific impacts on valley elderberry longhorn beetle, tricolored blackbirds, bats, special-status plants, riparian habitat, and valley needlegrass grassland to a less-than-significant level under the "Land" portion of the project. Mitigation measures in Section 3B.3, "Biological Resources - Water," would reduce impacts on vernal pool fairy shrimp, western spadefoot toad, northwestern pond turtle, Swainson's hawk, and Sacramento Orcutt grass to a less-than-significant level under the "Water" portion of the project. However, even with implementation of the proposed mitigation and regional enforcement of the USACE "no-net-loss" standard, the value of the region as it relates to the long-term viability of these resources would be substantially diminished. The "Land" and "Water" portions of the project would result in a cumulatively considerable incremental contribution to significant cumulative biological resources impacts, including the loss and degradation of sensitive habitats, habitat for special-status wildlife, and habitat for special-status plants; and loss/ displacement of special-status wildlife.

Fisheries

The assignment of water supplies from NCMWC in the Sacramento River Basin would not adversely affect candidate, sensitive, or special-status fish species. The proposed addition of a new point of diversion and change in CVP delivery schedule as part of the Off-site Water Facility Alternatives are relatively minor when compared

to overall flows in the Sacramento River system, including total Delta inflow and outflow, and Delta CVP and SWP exports. The minor changes in hydrologic conditions would have only very minimal impacts on overall aquatic habitat quantity and quality. As a result, the Off-site Water Facility Alternatives when added to other water supply projects, including the EWA and Yuba River Accord, would result in cumulative benefits to this section of the Sacramento River. Downstream of Freeport, the minor reduction in flows attributed to the Off-site Water Facility Alternatives would be minimized by the addition of flows from other water supply projects considered in the cumulative analysis and the overall change in the delivery schedule. Therefore, the "Water" portion of the project would not result in a cumulatively considerable incremental contribution to a significant cumulative impact related to fisheries.

CLIMATE CHANGE

Emissions of greenhouse gases (GHGs) have the potential to adversely affect the environment because such emissions contribute, on a cumulative basis, to global climate change. The proper context for addressing this issue in an EIR/EIS is as a discussion of cumulative impacts, because although the emissions of one single project will not cause global climate change, GHG emissions from multiple projects throughout the world could result in a cumulative impact with respect to global climate change. In turn, global climate change has the potential to result in rising sea levels, which can inundate low-lying areas; affect rainfall and snowfall, leading to changes in water supply; and affect habitat, leading to adverse effects on biological resources.

Because of the length of the cumulative global climate change analysis, it is presented in this EIR/EIS as a stand-alone section. Accordingly, please see Sections 3A.4 and 3B.4, "Climate Change." Sections 3A.4 and 3B.4 contain an analysis of the projected GHG emissions from the "Land" and "Water" portions of the project with respect to their potential to contribute to global climate change (see Subsections 3A.4.1 in 3A.4). Additionally, Section 3A.4 contains an analysis of the potential effects of global climate change on the "Land" portion of the project based on available scientific data. The development assumptions for the GPA were included in the modeling of impacts described for the "Land" portion of the project.

CULTURAL RESOURCES

The cumulative context for cultural resources is defined as the SPA and the Sacramento Region, including Sacramento and El Dorado Counties and the Cities of Folsom and Rancho Cordova. Cultural resources in the project region generally consist of prehistoric sites, historic sites, historic structures, and isolated artifacts. During the 19th and 20th centuries, localized urbanization and intensive agricultural use in the region caused the destruction or disturbance of numerous prehistoric sites, while many structures now considered to be historic were erected. From the latter half of the 20th century to the present, prehistoric and historic structures have been disturbed and destroyed. During this period, the creation and enforcement of various regulations protecting cultural resources have substantially reduced the rate and intensity of these impacts; however, even with these regulations, cultural resources are still degraded or destroyed as cumulative development in the region proceeds.

The records search conducted for the "Land" portion of the project indicates that the entire SPA has been previously inventoried for cultural resources and that approximately 260 prehistoric and historic-era districts, sites, features, and isolated artifacts have been identified (Appendix E2). Cultural resources identified within the SPA include: (1) traces of early Native American habitation including lithic artifact scatters and bedrock mortars; and (2) the remains of historic-era activities, in particular, those related to Gold Rush-era and later mining operations. The latter consist of the remains of small placer and quartz mines, numerous ditches and remains of similar water conveyance infrastructure, cabin sites, and other structural foundations, tailings piles, and refuse scatters.

Under the "Land" portion of the project, identified resources constitute the remains of a long series of human activities from prehistoric habitation and resource processing, to early historic mining, ranching, and transportation. Although the entire SPA has been subjected to detailed archaeological surveys and historical

investigations, much of this research has been piece-meal. Most of the prehistoric and historic-era resources documented within the SPA have not been formally evaluated for significance per National Register of Historic Places (NRHP) and the California Register of Historical Resources (CRHR) criteria. Regardless of their association or eligibility, the large number of cultural resources documented indicates thin the SPA has long been the focus of intensive activity for thousands of years and due to its largely intact nature it is unique in the Sacramento/Folsom region. Construction that would be implemented as part of the "Land" portion of the project would likely result in direct adverse impacts to these resources.

The records search conducted for the "Water" portion of the project identified 19 sites that are situated within various portions of the Off-site Water Facilities Study Area (Appendix M). Many of these sites are potentially associated with the American River (Folsom) Placer Mining District. In addition to the sites identified in the records search, the Off-site Water Facilities Study Area also includes portions of White Rock Road, which at one time was part of the Lincoln Highway; a major overland transportation route between Carson City and Sacramento during the Gold Rush era. Construction of the "Water" portion of the project could disturb known cultural and historic resources. Mitigation outlined in Section 3B.2, Cultural Resources - Water," would reduce potentially significant impacts to known cultural resources to a less-than-significant level.

Implementation of mitigation measures identified for the "Land" portion of the project in Section 3A.5, "Cultural Resources," would substantially reduce the level of direct impacts on identified cultural resources, but not to a less-than-significant level. Ground-disturbing work would still result in direct impacts to cultural resources, some of which are likely to be eligible for listing on the CRHR and NRHP. The State CEQA Guidelines (CCR Section 15126.4 [b][2]) state that a project which causes a substantial adverse change in the significance of a unique archaeological resource or an historical resource may have a significant effect on the environment. In some circumstances, depending on the significance of the resource, even the requirement for documentation of an archaeological resource or historical resource may not be sufficient to reduce the impact below the level of significance. Therefore, the "Land" portion of the project would result in a cumulatively considerable incremental contribution to the regional loss of known prehistoric and historic-era sites in the project vicinity.

The density of documented resources within the SPA and in the vicinity of the off-site elements under the "Land" portion of the project suggests that the entire project footprint is also sensitive for previously unidentified and currently unknown cultural resources. As-yet-undiscovered subsurface cultural resources might also underlie the booster pump station site, alternative WTP sites, and conveyance pipeline alternative alignments under the "Water" portion of the project. Mitigation measures contained in Sections 3A.5 and 3B.5, "Cultural Resources," would reduce project-related impacts on as-yet-undiscovered cultural resources to less-than-significant levels. However, undiscovered cultural resources may underlie one or more of the other related project sites, and it is unknown whether the related projects would implement appropriate mitigation. Furthermore, even after mitigation is implemented, it may be impossible to avoid the cultural resource, and a substantial adverse change in the significance of the resource (such as damaging or destroying the qualities that make it significant) could result. Therefore, the related projects could result in potentially significant cumulative impacts on undocumented cultural resources within the project vicinity. In this context, the "Land" and "Water" portions of the project could result in a cumulatively considerable incremental contribution to a significant cumulative impact.

The proposed GPA would change permitted densities, but would not change the physical locations identified for Single Family, Multi-family Medium Density, and Multi-family High Density development in the existing Folsom General Plan. For issue areas (such as cultural resources) that are related to land coverage, there would be no change from the City's existing General Plan.

ENVIRONMENTAL JUSTICE

Past, present, and probable future projects used for this cumulative analysis are restricted to those projects that have occurred or are planned to occur within the Cities of Folsom and Rancho Cordova boundaries, Sacramento County, and El Dorado Hills. According to the Council on Environmental Quality and U.S. Environmental

Protection Agency (EPA) guidelines, a minority population is present in a study area if the minority population of the affected area exceeds 50%, or if the minority population percentage of the affected area is meaningfully greater than the minority population percentage in the general population or other appropriate unit of geographic analysis. Under the same guidelines, a low-income population exists if a study area is composed of 50% or more people living below the poverty threshold, as defined by the U.S. Census Bureau, or if the percentage of people living below the poverty threshold in the study area is substantially greater than the poverty percentage of the general population or other appropriate unit of geographic analysis.

As discussed in Section 3A.6, "Environmental Justice - Land," no minority population exceeds 50% in Folsom, Sacramento County, or El Dorado Hills. The median household and per capita income and the poverty rate in Folsom and El Dorado Hills is less than that of Sacramento County, and the Folsom and El Dorado Hills' median household and per capita income and poverty rate is not meaningfully greater than the county's rate. Therefore, Implementation of the "Land" portion of the project would not cause a disproportionately high and adverse impact on minority and low-income populations.

A portion of the alternative conveyance pipeline alignments under the "Water" portion of the project would cross through an area identified as a low-income community south of Mather Airport. Poverty rates for this area are expected to decrease substantially as a result of new development and redevelopment activities with implementation of the *Mather Airport Master Plan.* In addition, these conveyance pipeline alternative alignments would be underground and would not create a nuisance or other adverse effects on low-income and minority populations.

Therefore, the "Land" and "Water" portions of the project and related projects would not contribute to disproportionate placement of environmental impacts on low-income and minority populations or communities and no cumulatively considerable impacts would result.

GEOLOGY, SOILS, MINERALS, AND PALEONTOLOGICAL RESOURCES

Geology and Soils

The "Land" and "Water" portions of the project and the related projects are located within the western margin of the Sierra Nevada foothills and the eastern margin of the Sacramento Valley. The geologic formations and soil types vary depending on project location, and therefore are site-specific. The SPA is not underlain by or adjacent to any known faults; however, structures in the SPA could be subject to seismic ground shaking from an earthquake along active faults in Lake Tahoe. In addition, the SPA is underlain by expansive soils and subject to seasonal subsurface water flows from surface infiltration that could adversely affect development. The booster pump station, alternative WTP sites, and alternative pipeline conveyance alignments under the "Water" portion of the project are also subject to seismic ground-shaking and underlain by expansive soils as wells as corrosive soils. Implementation of mitigation measures contained in Sections 3A.7 and 3B.7, "Geology, Soils, Minerals, and Paleontological Resources," would reduce these impacts to less-than-significant levels through completion of site-specific geotechnical studies and implementation of construction and design measures developed in response to the studies, in addition to compliance with the California Building Standards Code.

Implementation of the various related projects and other projects in the region could expose additional structures and people to seismic and soils hazards. However, each project considered in this cumulative analysis must individually meet building code requirements as well as the requirements of local policies (i.e., grading and erosion control plans), and therefore no additive effect would result and no cumulatively considerable impact related to seismic or soil hazards would occur. Implementation of the "Land" and "Water" portions of the project would not create additional facilities under increased risk of hazards and would not result in a cumulatively considerable incremental contribution to a significant cumulative impact related to geology and soils. The proposed GPA would change permitted densities, but would not change the physical locations identified for Single Family, Multi-family Medium Density, and Multi-family High Density development in the existing

Folsom General Plan. For issue areas (such as geology, soils, minerals, and paleontological resources) that are related to land coverage, there would be no change from the City's existing General Plan.

Mineral Resources

The presence of mineral resources is dependent on the type of geologic formation, which varies from location to location and therefore is site-specific. Some of the related projects contain sources of aggregate materials. None of the related projects contain potential sources of kaolin clay. The majority of the SPA is classified by the California Division of Mines and Geology (CDMG) as Mineral Resource Zone (MRZ) MRZ-3 for construction aggregate, "areas containing mineral deposits, the significance of which cannot be evaluated from existing data." The western third of the SPA contain areas where piles of cobbles were deposited during dredger gold mining operations in the 1800s and early 1900s. Similar piles of dredge tailings are present in nearby areas of Rancho Cordova, which are actively being mined, and the proposed Teichert, Walltown, and DeSilva-Gates quarries south of White Rock Road are proposed for mining as an aggregate sand and gravel resource. However, the on-site dredge tailings are located primarily within the Alder Creek drainage. Alder Creek is a perennial watercourse, and its drainage and riparian resources are protected by both Sacramento County and City of Folsom General Plan policies and ordinances. Furthermore, in 2003, the City of Folsom determined that because it did not have any active mining operations, and because none were expected in the future, that it would not update its California Surface Mining and Reclamation Act ordinance. The SPA is not delineated as an area of known mineral resources in either the City of Folsom or Sacramento County General Plans. Finally, the Alder Creek dredge tailings are not present in a large enough concentration that would warrant an economically viable on-site mining operation. Therefore, implementation of the "Land" portion of the project would not contribute substantially to a regional loss of aggregate sand and gravel resources and would not result in a cumulatively considerable incremental contribution to a significant cumulative impact related to these mineral resources.

The western edge of the SPA is zoned MRZ-3 for kaolin clay in an area that roughly corresponds to the location of the Ione Formation in the SPA. The Ione Formation is known to contain kaolin clay in other locations in northern California (i.e., Amador County). Currently it is unknown whether or not an economically valuable deposit of kaolin clay is present. If it were present, the deposit would be unavailable for mining following project implementation, because urban development is planned throughout the area where the Ione Formation occurs in the SPA. Mitigation measures in Section 3A.7, "Geology, Soils, Minerals, and Paleontological Resources - Land," would require studies to determine whether or not an economically valuable source of kaolin clay is present in the SPA. However, this mitigation would not reduce the level of impacts associated with the loss of kaolin clay, if it is present. The only occurrence of the Ione Formation in Sacramento County is located in the SPA. However, the Ione Formation occurs in other locations along Sierra Nevada foothills south of the SPA, from Amador County to Camanche Reservoir in Calaveras County. Kaolin clay is being mined at several locations within the Ione Formation in Amador County. Because the deposits of kaolin clay in the state occur in a very limited geographic area, the "Land" portion of the project could result in a cumulatively considerable incremental contribution to a significant cumulative impact (if kaolin clay is present in the SPA).

A review of available Sacramento County mineral resource maps indicates that facilities proposed as part of the "Water" portion of the project would not impede access to these delineated mineral resources within the eastern portions of Sacramento County. Although portions of the conveyance pipeline alternative alignments would travel in close proximity to several areas identified as containing mineral resources classified as MRZ-2; given that these alignments would be confined to the existing roadway rights-of-way, their location would not contribute to any increased losses in the availability of known mineral resources. Therefore, the "Water" portion of the project would have no impacts related to mineral resources and no cumulatively considerable impacts would occur.

Paleontological Resources

Fossil discoveries resulting from excavation and earth-moving activities associated with development are occurring with increasing frequency throughout the state. The value or importance of different fossil groups varies

depending on the age and depositional environment of the rock unit that contains the fossils, their rarity, the extent to which they have already been identified and documented, and the ability to recover similar materials under more controlled conditions (such as for a research project). Unique, scientifically-important fossil discoveries are relatively rare, and the likelihood of encountering them is site-specific and is based on the type of specific geologic rock formations found underground. These geologic formations vary from location to location.

A records search of the University of California Museum of Paleontology's Paleontology Collections database in Berkeley, California, did not identify any previously recorded fossil localities within the SPA or within the alternative WTP sites or conveyance pipeline alternative alignments. Most of the SPA and the off-site elements are underlain by the Salt Springs Slate, Copper Hill Volcanics, and Gopher Canyon Volcanics. Because of the way in which these rocks formed, they would not contain vertebrate fossils or fossil plant assemblages. However, the western edge of the SPA is underlain by Eocene-age sediments of the Ione Formation, the off-site detention basin west of Prairie City Road would be located within the Mehrten Formation, and the Off-site Water Facilities Study Area would include elements in the Riverbank, Ione, and Mehrten Formations. Because of the large number of fossils that have been recovered from the Mehrten, Ione, and Riverbank Formations throughout the Central Valley, they are considered paleontologically sensitive rock units, thus suggesting that there is a potential for uncovering additional similar fossil remains during construction-related earthmoving activities in these formations in the SPA and off-site detention basin. Mitigation measures are contained in Sections 3A.7 and 3B.7, "Geology, Soils, Minerals, and Paleontological Resources," that would reduce impacts on previously undiscovered paleontological resources to less-than-significant levels.

When unique, scientifically-important fossils are encountered by construction activities, the subsequent opportunities for data collection and study generally provide a benefit to the scientific community. Therefore, because of the site-specific nature of unique paleontological resources; the low probability that any project would encounter unique, scientifically-important fossils; and the benefits that would occur from recovery and further study of those fossils if encountered, development of the related projects and other development in the region are not considered to result in a cumulatively considerable impact related to paleontological resources. Therefore, the "Land" and "Water" portions of the project would not result in a cumulatively considerable contribution to a significant cumulative impact related to paleontological resources.

HAZARDS AND HAZARDOUS MATERIALS

Health and safety impacts associated with the past or current uses of a project site usually occur on a project-by-project basis, rather than in a cumulative nature. Implementation of the "Land" and "Water" portions of the project could result in hazards and hazardous materials impacts related to exposure to on-site hazardous materials during construction development on a known hazardous materials site, and exposure to wildland fires. Within the SPA, impacts related to potential blast-related injuries during construction, exposure to electric and magnetic fields, and public health hazards from mosquitoes attracted by water features could occur. Construction of the "Water" alternatives could result in interference with adopted emergency response plans. However, mitigation measures identified in Sections A3.8 and B3.8, "Hazards and Hazardous Materials," would reduce the project-specific health and safety hazards to less-than-significant levels. Under cumulative conditions, implementation of the "Land" and "Water" portions of the project in conjunction with development of related projects is not anticipated to present a public health and safety hazard to residents.

The "Land" and "Water" portions of the project and related projects would all involve the storage, use, disposal, and transport of hazardous materials to varying degrees during construction and operation. Impacts from these activities are less than significant for the project because the storage, use, disposal, and transport of hazardous materials are extensively regulated by various Federal, state, and local laws, regulations, and policies. It is foreseeable that the project and the related projects would implement and comply with these existing hazardous materials laws, regulations, and policies. Therefore, the related projects would not cause a cumulative impact, and the "Land" and "Water" portions of the project would not result in a cumulatively considerable incremental contribution to a cumulative impact related to transport of hazardous materials. The proposed GPA would change

permitted densities, but would not change the physical locations or land uses identified for Single Family, Multi-family Medium Density, and Multi-family High Density development in the existing Folsom General Plan. For issue areas (such as hazards and hazardous materials) which are related to land coverage, there would be no change from the City's existing General Plan.

HYDROLOGY, WATER QUALITY, AND GROUNDWATER RESOURCES

Local hydrology, drainage, and water quality conditions are often affected by regional activities, in addition to local activities and related projects. Past and present projects from the Sierra Nevada (dams and reservoirs, mining operations, logging, urban development) to the Sacramento–San Joaquin Delta (water supply diversions, agricultural diversions, flood control projects, urban development, river channelization) affect hydrology and water quality conditions in Sacramento and El Dorado Counties. The following evaluation of cumulative hydrology and water quality impacts is made in light of the extent to which local and regional activities can affect hydrologic conditions in these counties. Implementation of the "Land" use portion of the project focuses on effects on water bodies in the project vicinity and immediately upstream and downstream and how the project and related projects may affect the hydrology and water quality conditions locally. The "Water" portion of the project includes water supply projects and larger statewide planning efforts that could substantially influence cumulative operational conditions along the Sacramento River. The potential cumulative impacts are discussed in detail below.

The proposed GPA would change permitted densities, but would not change the types of uses or physical locations identified for Single Family, Multi-family Medium Density, and Multi-family High Density development in the existing General Plan. For issue areas (such as hydrology and water quality) which are related to land coverage or type of use, there would be no change from the City's existing General Plan.

Surface Water Quality

Construction activities during implementation of the "Land" and "Water" portions of the project would involve extensive grading and movement of earth. Substantial construction-related alteration of on-site drainages could result in soil erosion and stormwater discharges of suspended solids, increased turbidity, and potential mobilization of other pollutants from project-related construction sites. This contaminated runoff could enter Alder Creek, Buffalo Creek, Coyote Creek, Carson Creek, or other on-site drainage channels and ultimately drain off-site. Intense rainfall and associated stormwater runoff in relatively flat areas could result in short periods of sheet erosion within areas of exposed or stockpiled soils. If uncontrolled, these soil materials could cause sedimentation and blockage of drainage channels. Accidental spills of construction-related contaminants, such as fuels, oils, paints, solvents, cleaners, and concrete, could occur during construction activities in the SPA, resulting in surface soil contamination. The "Land" and "Water" portions of the project must prepare a storm water pollution prevention plan (SWPPP) consistent with the existing statewide National Pollutant Discharge Elimination System (NPDES) discharge permits from the Central Valley Regional Water Quality Control Board (RWQCB). Implementation of these regulatory requirements in addition to mitigation in Sections 3A.9 and 3B.9, "Hydrology and Water Quality," would reduce the potentially significant water quality and erosion impacts from construction activities to a less-than-significant level. Although there are no assurances that the related projects would incorporate the same degree or methods of treatment as the project, each related project that would discharge stormwater runoff would be required to comply with NPDES discharge permits from the Central Valley RWQCB. Therefore, the "Land" and "Water" portions of the project would not result in a cumulatively considerable incremental contribution to a significant cumulative impact.

Implementation of the "Land" and "Water" portions of the project would create new impervious surfaces and landscape features that would increase the volume of runoff that could cause or contribute to long-term discharges of urban contaminants (e.g., sediment, oil and grease, fuel, trash, pesticides, fertilizer). This increase in impervious surface would increase the peak discharge rate of stormwater runoff generated in the SPA and from areas upstream (e.g., contribution of flow from off-site watersheds to Alder Creek within the SPA). Under the

"Water" portion of the project, all drainage runoff from the alternative WTP sites would enter Buffalo Creek, which flows west and is tributary to the Lower American River. The Low Impact Development (LID) principles summarized in Section 3A.9, "Hydrology and Water Quality - Land," and conformance with applicable state and local regulations regulating surface water runoff, including the procedures outlined in the Sacramento City/County Drainage Manual and the El Dorado County Storm Water Management Plan, would reduce potential water quality and erosion impacts from an increase in stormwater runoff to a less-than-significant level. Under the "Water" portion of the project, implementation of mitigation measures in Section 3B.9, "Hydrology and Water Quality - Water," and conformance with applicable state and regulations regulating surface water runoff, including the procedures outlined in the Sacramento City/County Drainage Manual, would reduce the impacts to a less-than-significant level. Although there are no assurances that the related projects would incorporate the same degree or methods of treatment as the project, each related project that would discharge stormwater runoff would be required to comply with NPDES discharge permits from the Central Valley RWQCB, which adjusts requirements on a case-by-case basis to avoid significant degradation of water quality. Therefore, the "Land" and "Water" portions of the project would not result in a cumulatively considerable incremental contribution to a significant cumulative impact related to surface water quality.

Implementation of the "Land" portion of the project would convert a large area of undeveloped land to residential and commercial uses, thereby changing the amount and timing of potential long-term waste discharges in stormwater runoff to Alder Creek, Buffalo Creek, Coyote Creek, Carson Creek, and other drainages on- and off-site. The storm drainage system for the project is designed to direct runoff flows into on-site detention basins (and one off-site basin west of Prairie City Road), and would incorporate water quality treatment. Under the "Water" portion of the project, storm drainage system for the White Rock WTP or Folsom WTP would be incorporated into project designs. The incorporation of LID principles summarized in Section 3A.9, "Hydrology and Water Quality - Land," and conformance with applicable state and local regulations regulating surface water runoff, including the procedures outlined in the Sacramento City/County Drainage Manual and the El Dorado County Storm Water Management Plan, would reduce the potentially significant impact associated with potential long-term water quality effects of urban runoff to less-than-significant levels. Under the "Water" portion of the project, implementation of mitigation measures in Section 3B.9, "Hydrology and Water Quality - Water ," and conformance with applicable state and regulations regulating surface water runoff, including the procedures outlined in the Sacramento City/County Drainage Manual, would reduce the impacts to a less-than-significant level. Therefore, the "Land" and "Water" portions of the project would not result in a cumulatively considerable incremental contribution to a significant cumulative impact related to surface water quality.

Surface Water Flows

The Off-site Water Facility Alternatives, along with other existing, planned, and foreseeable future projects and other changes to water management and system operations (e.g. north of Delta Storage, isolated conveyance), could directly affect Sacramento River flows by diverting water from the Sacramento River, or indirectly by inducing changes in Delta hydrologic conditions that could trigger changes in CVP and SWP reservoir operations and pumping from the south Delta.

Diversion of surface water at Freeport as opposed to NCMWC would not be considered an additional diversion, but rather a modification of an existing diversion under a new M&I delivery schedule. Table 3B.9-3 provides an indication of the changes in monthly diversions on the Sacramento River as a result the changes in the delivery schedule and reduced return flow. As shown, the modeled values indicate only minor fluctuations in monthly river flow would occur in conjunction with cumulative conditions and operation of the "Water" portion of the project. The change in the delivery schedule would require minor changes in releases from upstream CVP facilities, but would not contribute to discernable decreases (<0.04%) in Delta inflow. Therefore, changes in downstream Sacramento River flow would be minor and would not conflict with other water management objectives (e.g. BDCP, OCAP) or beneficial uses (e.g. cold water fisheries).

The amount of carryover storage has an effect on the balance between CVP and SWP long-term average annual and dry year exports. Reduced reservoir carryover storage could result in reduced SWP and CVP water deliveries in subsequent years with certain hydrologic conditions. In the case of the Off-site Water Facility Alternatives, the change to an M&I delivery schedule would incrementally add to carryover storage in CVP reservoirs by reducing diversions in summer months and more evenly distributing demand throughout the year.

Based on the changes in delivery schedule shown in Table 3B.9-3 and related effects to surface flows within the Sacramento River, the impacts of the "Water" portion of the project on hydrologic conditions within the Delta are not expected to adversely affect CVP and SWP reservoir operations or pumping in the south Delta. Because the "Water" portion of the project would not divert more than 10 cubic feet per second on average from the Sacramento River and that this diversion consists of existing CVP contract water, its direct potential maximum effect on flows of the Sacramento River and Delta would be minor. Conceivably, if other water transfer projects are proposed, they could contribute to some extent to further changes in Sacramento River flow. In addition, other larger water supply projects, such as Site Reservoir and the Bay Delta Conservation Plan, could contribute to further reductions in Sacramento River flows in the long-term. However, based on the magnitude of change in river flows associated with the Off-site Water Facility Alternatives, these changes would not result in a cumulatively considerable incremental contribution to a significant cumulative impact related changes in Delta inflow and outflow that could otherwise interfere with any CVP and SWP export diversions.

Flood Protection

The SPA is not in an area protected by levees and is not located within the Folsom Dam inundation zone; however, there are two ponds within the site and one pond upstream of the site. These ponds are formed behind existing on-site dams in topographically low areas along existing drainages. The height of the two dams and/or volume of water in the associated impoundments are unknown. Additionally, evaluation of the dams has not been conducted to determine stability, potential for risk of failure, and/or estimated area of downstream inundation in the event of failure. Implementation of mitigation described in Section 3A.9, "Hydrology and Water Quality - Land," would reduce the potential for increased risk of flooding as a result of dam failure to a less-than-significant-level because the small dams and associated impoundments within and upstream of the SPA meet minimum stability requirements and not exposure of people or structures to a significant risk of flooding.

The SPA is located within an area that at this time is not included in the 200-year floodplain as defined by California Water Code Section 9610[a], pursuant to Senate Bill (SB) 5. Furthermore, site-specific modeling has been performed to determine where the 200-year floodplain in the SPA would be located under pre-development and post-development conditions. Therefore, implementation of the "Land" portion of the project would not subject people and/or structures to impacts related to flooding as a result of a 200-year storm because the project development would comply with SB 5 criteria protecting the proposed development from the 200-year flood.

As discussed in Section 3B.9, "Hydrology and Water Quality - Water," the alternative WTP sites would not be located in a 100-year floodplain. Portions of the conveyance pipeline alternative alignments would be located within a 100-year floodplain; however, these facilities would be located underground. Therefore, the "Water" portion of the project would result in less-than-significant impacts related to the increased risk of flooding and flood hazards.

Some of the related projects in the region may also result in the placement of structures in areas designated as 100- or 200-year floodplains. However, as with the "Land" portion of the project, the related projects would be required by law to comply with all applicable state and local regulations regarding flooding and flooding hazards, including protection of residents and workers from 100- and 200-year flood flows. Therefore, implementation of the related projects would not result in a cumulative impact, and the "Land" portion of the project's contribution to the impact from 100- and 200-year flood flows would not be cumulatively considerable.

Surface Drainage

Implementation of the "Land" portion of the project would convert a large area of undeveloped land to residential and commercial uses, which could substantially alter drainage courses and runoff patterns from existing conditions. Compacting soils and constructing impervious surfaces can reduce the net amount of infiltration of rain water into the soil, thereby increasing runoff rates and volumes. As discussed above, the storm drainage system for the project is designed to direct runoff flows into on-site detention basins (and one off-site basin west of Prairie City Road), and would incorporate water quality treatment. The incorporation of LID principles summarized in Section 3A.9, "Hydrology and Water Quality - Land," and conformance with applicable state and local regulations regulating surface water runoff, including the procedures outlined in the Sacramento City/County Drainage Manual and the El Dorado County Storm Water Management Plan, would reduce the long-term impacts from changes in drainage and runoff patterns in the SPA to a less-than-significant level. As a result, no adverse project-specific impacts would occur.

Under the "Water" portion of the project, operation of the WTP alternatives would contribute additional stormwater runoff to Buffalo Creek, resulting in potential downstream flooding. Implementation of mitigation measures in Section 3B.9, "Hydrology and Water Quality - Water," and conformance with applicable state and regulations regulating surface water runoff, including the procedures outlined in the Sacramento City/County Drainage Manual, would reduce the long-term impacts from changes in drainage and runoff patterns to a less-than-significant level.

In other new developments within Sacramento County, Folsom, and Rancho Cordova, stormwater conveyance would also consist of surface runoff to detention basins, swales, or other detention facilities. Such new development, like the project, would be required to comply with the requirements of the design criteria identified in the Stormwater Quality Design Manual for the Sacramento and South Placer Regions. In addition, cumulative impacts of related projects would undergo separate environmental review to ensure that design criteria facilities are included as part of those projects. Therefore, the "Land" and "Water" portions of the project would not result in a cumulatively considerable incremental contribution to a significant cumulative impact related to changes in drainage and runoff patterns and stormwater conveyance.

Groundwater Recharge

Planned development under the "Land" portion of the project would include increases in impervious surfaces and the amount of surface runoff generated by proposed development. Soils in the SPA and surrounding area have a poor capacity for groundwater recharge, with most of the substantial recharge occurring along active stream channels. Those areas within the SPA that are most conducive to groundwater recharge, such as the Alder Creek stream and tributary corridors as well as the retention basins, would be sited and designed to maximize infiltration. Furthermore, no new wells would be established for domestic use, and increased seasonal groundwater recharge from landscape irrigation activities would occur. Impacts on groundwater recharge would be less-than-significant. Therefore, the "Land" portion of the project would not result in a cumulatively considerable incremental contribution to a significant cumulative impact related to groundwater recharge.

Groundwater Resources

Construction of the conveyance pipeline alternative alignments, booster pump station, and WTP alternatives would, at times, require dewatering of shallow, perched groundwater in the immediate vicinities of excavations and installation of underground features at a limited number of areas where groundwater depths are shallow. Groundwater withdrawn from the construction areas would be subsequently discharged to local waterways or drainage ditches, or via land application, and could result in soil erosion and stormwater discharges of suspended solids, increased turbidity, and potential mobilization of other pollutants from project-related construction sites. Implementation of mitigation measures in Section 3B.17, "Groundwater Resources - Water," would reduce impacts associated with construction dewatering to a less-than-significant level. Because construction dewatering

of shallow groundwater would be temporary, it would not act in combination with other projects to result in a cumulatively considerable incremental contribution to a significant cumulative impact on local groundwater resources.

Construction of the White Rock WTP or Folsom Boulevard WTP under the "Water" portion of the project would include increases in impervious surfaces and the amount of surface runoff generated by proposed development. However, these impermeable surfaces would be limited in extent to less than 0.5-acre of the 10-acre alternative WTP sites (including buildings, paved roads, storage and treatment facilities, and parking lots) and only a portion of the well sites (including access roads and auxiliary facilities). This area would be very small in comparison to adjacent areas that would remain open and permeable. Impacts on groundwater recharge from implementation of the "Water" portion of the project would be less-than-significant. Therefore, the "Water" portion of the project would not result in a cumulatively considerable incremental contribution to a significant cumulative impact related to groundwater recharge.

Implementation of the "Water" portion of the project would not construct new wells or require groundwater to meet water demands of the "Land" portion of the project. However, operation of the "Water" portion of the project could indirectly contribute to an increase in the volume of groundwater pumped by SCWA within the South American Subbasin in the future. Other projects that may contribute to future cumulative impacts include: new development associated with the Sacramento County General Plan Update, the Long-Term EWA Program, East Sacramento County Groundwater Replacement Project, and SCWA Zone 40 Conjunctive-Use Program. Under future cumulative conditions (beyond 2030), other incremental water demands from developments within the unincorporated portions of Sacramento County in conjunction with new growth within the City's of Rancho Cordova and Elk Grove could place additional demands on local groundwater. These additional demands as contemplated in Sacramento County's General Plan EIR for the Preferred Alternative when combined with SCWA's incremental reduction in capacity within the Freeport Project could lead to cumulatively considerable impacts to local groundwater resources by exceeding the groundwater basin's safe yield of 273,000 AFY.

In the Sacramento County General Plan Update EIR, the County identified an additional water demand of 31,633 AFY for the proposed Preferred Alternative. This additional demand, if solely supplied through groundwater, and combined with other existing groundwater demands is estimated at 262,280 AFY in 2030 and would exceed the sustainable yield for the Central Basin. The largest component of the total 31,633 AFY for SCWA Zone 40's new water demand is almost entirely created by the Jackson and Grant Line East New Growth Areas and is an order of magnitude larger than the purveyor with the next largest demand (California American Water Suburban/Rosemont) at 2,342 AFY demand predicted for the Central Basin.

The County's General Plan EIR notes that SCWA's Zone 40 is allocated 40,900 AFY of groundwater from the Central Basin with the completion of the Freeport Project and, as provided in the County's draft General Plan Update EIR, SCWA is not proposing any new groundwater supply in excess of this allocation to support growth in the General Plan Update's Preferred Alternative. At this time, SCWA is proposing additional water conservation, use of recycled water, and a robust conjunctive use plan that identifies an active groundwater banking program during wet weather and increased groundwater pumping during dry periods. In addition, the draft General Plan Update EIR identifies an additional policy requiring that a water supply plan demonstrating that new growth within the Jackson and Grant Line East New Growth Areas will not exceed the sustainable yield of the Central Groundwater Basin be approved prior to development.

Although the County's Preferred Alternative, General Plan (2007), has not been formally adopted, the potential indirect impacts to groundwater resources created by the Off-Site Water Facility Alternatives could contribute a cumulative demand for groundwater resources. Beyond 2030, the combined demand for groundwater during dry years could exceed the safe yield of the Central Basin, thereby resulting in a significant, cumulatively considerable impact. At this time, the City is unable to confirm whether potential future groundwater impacts could be reduced to less than significant levels. Based on this circumstance, the City concludes that the Off-site

Water Facility Alternatives could indirectly contribute to potentially cumulative, significant and unavoidable impacts to the South American Groundwater Subbasin beyond 2030.

LAND USE AND AGRICULTURAL RESOURCES

The SPA is generally located in eastern Sacramento County immediately south of the Folsom city limits and west of the Sacramento/El Dorado County line. Under the "Water" portion of the project, the alternative WTP sites are located within unincorporated Sacramento County and the conveyance pipeline alternative alignments would be installed within the boundaries of the City of Rancho Cordova and unincorporated Sacramento County. Proposed, planned, and approved development in El Dorado and Sacramento Counties and regional development anticipated by the SACOG Blueprint must be considered for the purpose of evaluating land use impacts on a cumulative level (Exhibits 4-1 and 4-2). Under cumulative conditions, future projects will increase development and provide additional housing, employment, shopping, and recreational opportunities.

The SPA consists of livestock grazing lands, and there is only one existing single-family residence and associated agricultural outbuildings located on the western side of the SPA. No residential land uses are located on the alternative WTP sites or within the conveyance pipeline alternative alignment under the "Water" portion of the project. Therefore, implementation of the "Land" and "Water" portions of the project would not physically divide an established community and it would not contribute to a cumulative impact on this basis.

Future growth under cumulative conditions may result in a variety of physical impacts related to consistency with adopted land use plans. Impacts involving adopted land use plans or policies and zoning generally would not combine to result in cumulative impacts. The determination of significance for impacts related to these issues, as described by Appendix G of the State CEQA Guidelines, and referenced earlier in Sections 3A.10 and 3B.10, "Land Use and Agricultural Resources," is whether a project would conflict with any applicable land use plan or policy adopted for the purpose of avoiding or mitigating environmental impacts. Such a conflict is site-specific; it is addressed on a project-by-project basis. Implementing the "Land" and "Water" portions of the project would not result in significant land use planning impacts, and the project's ultimate consistency with adopted local land use plans, policies, and zoning is provided for through entitlements to revise the City of Folsom General Plan and Zoning Code under the "Land" portion of the project and the Sacramento County General Plan and Zoning Code.

Any land use inconsistencies of future projects, by themselves, are not considered a significant cumulative effect because it is a land use regulation, not an environmental impact. However, implementation of those plans and policies adopted for the purpose of avoiding or mitigating environmental impacts could lead to physical environmental impacts, which are considered in the appropriate sections of this EIR/EIS. Because land use impacts would occur on a project-specific basis rather than a cumulative basis, the project would not contribute to cumulatively considerable land use impacts. The proposed GPA would change permitted densities, but would not change permitted uses or the physical locations identified for Single Family, Multi-family Medium Density, and Multi-family High Density development in the existing Folsom General Plan. For issue areas (such as land use and agricultural resources) which are related to land coverage, there would be no change from the City's existing General Plan.

Agricultural Resources

Land in the project vicinity has been converted from agricultural uses to urban development over the last 50 years. Because of the soil types, land in the project vicinity is generally most suitable for grazing land, rather than intensive agriculture such as row crops. Approximately 187,102 acres of land in Sacramento County was under Williamson Act contracts in 2007 (California Department of Conservation [DOC] 2008:26). Of these lands, approximately 10,605 acres were in the nonrenewal process (DOC 2008:29). The nonrenewal process is the most common mechanism for termination of Williamson Act contract lands and most Williamson Act contracts are terminated through nonrenewal expiration. In Sacramento County, approximately 406 acres of land under of

Williamson Act contracts entered the nonrenewal process, and the amount of contract land terminated through nonrenewal expirations was approximately 524 acres as of 2007 (DOC 2008:34, 35).

Under the "Land" portion of the project, approximately 2,493 acres of the SPA consists of agricultural lands under existing Williamson Act contracts. Notices of nonrenewal were filed on these parcels in 2004 and 2006; as a result, these existing contracts will expire in 2014 and 2016, respectively. Under the "Water" portion of the project, the White Rock WTP site is under an existing Williamson Act contract, and a notice of nonrenewal was filed on this parcel (APN 072-0060-052-000) and the existing contract will expire in 2018. Implementation of the "Land" and "Water" portions of the project would require the cancellation of one or more of these Williamson Act contracts before their expiration date because the proposed land and water uses would not be permitted under the existing contracts. No feasible mitigation measures are available to reduce impacts associated with the cancellation of these Williamson Act contracts to a less-than-significant level.

In the vicinity of the SPA and Off-site Water Facilities Study Area, the only agricultural lands under existing Williamson Act contracts are south of White Rock Road. Nearby proposed projects, including the Teichert and Walltown quarries, would require cancellation of lands under Williamson Act contracts. Therefore, the impact of these related projects would be cumulatively considerable (i.e., significant), and the "Land" and "Water" portions of the project would result in a cumulatively significant incremental contribution to this cumulatively significant and unavoidable impact. It should be noted that the Williamson Act contract for the DeSilva-Gates Quarry project specifically lists mining as a compatible use under the terms of the existing contract and no cancellation of this contract would be required (Sacramento County 2007a).

The Sacramento County Important Farmland map, published by DOC's Division of Land Resource Protection, designates the SPA, the off-site freeway interchange improvements, the sewer force main, and the detention basin under the "Land" portion of the project, and the alternative WTP sites and conveyance pipeline alternative alignments under the "Water" portion of the project, as Grazing Land and/or Urban and Built-Up Land (DOC 2006). The two off-site roadway extensions from the Folsom Heights property into El Dorado Hills are designated by the El Dorado County Important Farmland Map as Grazing Land and Urban and Built-Up Land. These farmland designations are not considered Important Farmland under CEQA (California Public Resources Code Sections 21060.1 and 21095 and State CEQA Guidelines Appendix G). Therefore, the "Land" and "Water" portions of the project would not result in a cumulatively considerable incremental contribution to a significant cumulative impact related to conversion of Important Farmland to nonagricultural uses.

NOISE

CUMULATIVE IMPACTS - NOISE

When determining whether the overall noise (and vibration) impacts from related projects would be cumulatively significant and whether the project's incremental contribution to any significant cumulative impacts would be cumulatively considerable, it is important to note that noise and vibration are localized occurrences; as such, they decrease rapidly in magnitude as the distance from the source to the receptor increases. Therefore, only those related projects that are in the direct vicinity of the "Land" and "Water" portions of the project and those that are considered influential in regards to noise and vibration (e.g., not located where ambient conditions are dominated by traffic noise from U.S. 50 and relatively large in size) would have the potential to be considered in a cumulative context with the project's incremental contribution (e.g., Easton, Carson Creek, City Corporation Yard, and the Teichert, Walltown, and DeSilva Gates quarries).

Temporary, Short-Term Exposure of Sensitive Receptors to Increased Equipment Noise

Construction equipment noise from the aforementioned related projects would be similar in nature and magnitude to those discussed from the "Land" and "Water" portions of the project in Section 3A.11 and 3B.11, "Noise." Specifically, noise levels from on-site construction activities would fluctuate depending on the particular type,

number, and duration of usage for the varying equipment. The site preparation phase would be anticipated to generate the most substantial noise levels as the on-site equipment associated with grading, compacting, and excavation tend to be the loudest. Although detailed information is not currently available, construction of the related projects would be anticipated to result in noise levels of approximately 87 dB L_{eq} and 90 dB L_{max} at 50 feet from the simultaneous operation of heavy-duty equipment, which could exceed applicable standards at nearby sensitive receptors and/or result in substantial increases in ambient noise levels especially during the more noise-sensitive hours of the day. While temporary, short-term construction source noise levels from the related projects could be considered exempt in the City of Folsom and the County of Sacramento if such noise would only occur during the daytime hours, there is no guarantee that all of the related projects would include such restrictions, and the County of El Dorado has not adopted a daytime construction noise exemption. Therefore, the related projects could generate significant impacts related to short-term exposure of sensitive receptors to increased equipment noise. Construction of the "Land" and "Water" portions of the project could also result in a significant impact from temporary, short-term equipment noise levels in the direct vicinity and possible during the same time frame as the related projects. Implementation of Mitigation Measures in 3A.11 and 3B.11, "Noise," would limit construction activities to daytime hours and require the construction of temporary noise barriers; however, these measures would not be sufficient to avoid significant construction noise impacts. Thus, the incremental contribution of the "Land" and "Water" portions of the project to this significant cumulative impact would be cumulatively considerable.

Temporary, Short-Term Exposure of Sensitive Receptors to Potential Groundborne Noise and Vibration

Groundborne noise and vibration levels from construction of the aforementioned related projects would be similar in nature and magnitude to those discussed in section 3A.11 and 3B.11, "Noise." Specifically, construction activities would result in varying degrees of temporary groundborne noise and vibration, depending on the specific construction equipment used and activities involved (see, for example, Table 3A.11-17). Although detailed information is not currently available, construction of the related projects would be anticipated to result in maximum groundborne noise and vibration levels associated with bulldozing and blasting activities. According to FTA, levels associated with the use of a large bulldozer and blasting are 0.089 and 1.13 in/sec PPV (87 and 109 VdB) at 25 feet, respectively. With respect to the prevention of structural damage, bulldozing would not exceed the Caltrans-recommended level of 0.2 in/sec PPV even at a distance of 25 feet. However, blasting could exceed this level within 80 feet of said activities based on FTA's recommended procedure for applying a propagation adjustment to these reference levels. In addition, with respect to prevention of human disturbance, bulldozing and blasting could exceed the FTA-recommended level of 78 VdB within 50 and 275 feet, respectively. The exact locations of bulldozing activities and blasting points have not been determined at this time; however, nearby sensitive receptors could be located within the distances modeled above that are correlated with the Caltrans- and FTA- recommended exceedance levels. Therefore, the related projects could result in a significant impact from short-term exposure of sensitive receptors to potential groundborne noise and vibration. As discussed in Sections 3A.11 and 3B.11, "Noise," construction of the "Land" and "Water" portion of the project would result in a significant impact from temporary, short-term groundborne noise and vibration levels in the immediate vicinity and possibly during the same time frame as the related projects. Implementation of Mitigation Measures contained in Sections 3A.11 and 3B.11, "Noise" would reduce this impact, but not to a less-than-significant level. Thus, the incremental contribution of the "Land" portion of the project to this significant cumulative impact would be cumulatively considerable. Under the "Water" portion of the project, construction-related blasting activities would be temporary and short-term and located a sufficient distance away from existing structures, including residencies, such that this impact would be less than significant.

Long-Term Exposure of Sensitive Receptors to Increased Stationary-Source Noise

Stationary-source noise from the aforementioned related projects would be similar in nature and magnitude to those discussed from the "Land" and "Water" portions of project in Sections 3A.11 and 3B.11 for mechanical HVAC equipment, emergency electrical generators, parking lot activities, loading dock and delivery activities, emergency facilities, and outdoor recreational and educational activities. With respect to the City Corporation

Yard, noise sources could include on-site truck and forklift activities (e.g., idling and circulating), generators, fans, air compressors, maintenance shops, metal fabricating shops, welders, cutting equipment, grinders, outdoor speakers, blowers, loading docks, and pallets dropping. New stationary noise sources at the booster pump station and White Rock WTP or Folsom Boulevard WTP under the "Water" portion of the project include generators, pumps, and heavy equipment. According to EPA and other documented references, noise levels for such equipment can range from approximately 76 to 91 dB at 3 feet from the source depending on the exact type and at 50 feet typical from 55 to 75 dB L_{eq} and from 80 to 84 dB L_{max} (EPA 1971). Operation of the related projects could result in the long-term stationary source noise levels that exceed applicable standards at nearby sensitive receptors and/or result in substantial increases in ambient noise levels. While these types of noise levels could be controlled and associated noise levels reduced at the source (e.g., noise walls, enclosures, located in shielded locations, properly equipped and maintained), there is no guarantee these would be included in all of the related projects. Therefore, a significant impact could occur from the related projects. As discussed in Sections 3A.11 and 3B.11, operation of the "Land" and "Water" portions of the project could result in a significant impact from long-term stationary source noise levels; however, implementation of Mitigation Measures in Sections 3A.11 and 3B.11 would reduce this impact to a less-than-significant level in the direct vicinity of the related projects. Thus, the incremental contribution of the "Land" and "Water" portions of the project to this significant cumulative impact would not be cumulatively considerable.

Long-Term Exposure of Sensitive Receptors to Increased Traffic Noise Levels

This analysis examines the potential for degradation of the existing ambient noise environment from project implementation based on thresholds contained in the CEQA checklist, which also encompass the factors taken into account for impacts under NEPA, where a 5 dBA increase at 50 dBA existing sound levels would be considered a significant impact, and a 3 dBA increase at 60 dBA existing sound levels would be considered a significant impact.

Implementation of the aforementioned related projects would result in an increase in ADT volumes on affected roadway segments and, consequently, an increase in traffic source noise. Traffic noise levels associated with the related projects were predicted for affected roadway segments using FHWA's Highway Noise Prediction Model (FHWA-RD-77-108) (FHWA 1978) and traffic data (e.g., ADT volumes, vehicle speeds, and percent distribution of vehicle types) from DKS Associates, Inc. and Caltrans. This model is based on the California vehicle noise (CALVENO) reference noise emission factors for automobiles, medium trucks, and heavy trucks, with consideration given to vehicle volume, speed, roadway configuration, distance to the receiver, and ground attenuation factors and does not assume any natural or human-made shielding (e.g., the presence of vegetation, berms, walls, or buildings). Table 4-8 summarizes the modeled traffic noise levels at the approximate road corridor boundary under future no project conditions, essentially the noise levels attributable only to the related projects including the quarry-related activities. In comparison to those levels shown in Table 3A.11-18 under the existing no project conditions, implementation of the related projects would result in substantial (e.g., 3 dB L_{dn}/CNEL where traffic noise levels range between 60 and 65 dB L_{dn}/CNEL, or 1.5 dB L_{dn}/CNEL where traffic noise levels are greater than 65 dB L_{dn}/CNEL) net increases along affected roadway segments. It is also important to note here that the addition of the quarry-related traffic alone under future conditions (i.e., compare no project [without quarry trucks] to no project [with quarry truck] in Table 4-8 below) results in substantial increases in traffic noise levels. Therefore, the related projects could result in a significant impact from long-term exposure of sensitive receptors to increased traffic noise levels. As discussed in Impact 3A.11-4, project operation would result in a significant impact from the long-term exposure of sensitive receptors to increased traffic noise levels on the same affected roadway segments, which for the purposes of that analysis, did not include quarry-related traffic. Implementation of Mitigation Measure 3A.11-4 would reduce this impact, but not to a less-than-significant level. In addition, even when considering the addition of quarry-related traffic under future conditions, implementation of the project would still result in substantial increases when comparing future no project with future plus project conditions as indicated in bold in Table 4-8 below.

Table 4-8
Summary of Modeled Traffic Noise Levels of the "Land" Portion of the Project Under Future (2030) No Project and Future Plus Project Conditions, With Quarry Truck Trips

Notes: CNEL = Community Noise Equivalent Level; dB = A-weighted decibels; L_{dn} = day-night average noise level; Δ = Change; NP = No Project; PP = Proposed Project Alternative; RIM = Resource Impact Minimization Alternative; CD = Centralized Development Alternative; RHD = Reduced Hillside Development Alternative; NF = No Federal Action Alternative

Bold: Represents the potential for substantial increase (e.g., 3 dB L_{dn}/CNEL where existing or projected future traffic noise levels range between 60 and 65 dB L_{dn}/CNEL, 1.5 dB L_{dn}/CNEL where existing or projected future traffic noise levels are greater than 65 dB L_{dn}/CNEL) in comparison to existing No Project conditions.

Refer to Appendix J for detailed modeling input data and output results.

Source: Data provided by AECOM in 2009

Over the long-term, operation of the "Water" portion of the project could generate a minimal number of new vehicle trips from employees traveling to and from the White Rock WTP or Folsom Boulevard WTP and routine maintenance and inspection activities of the conveyance pipeline and booster pump station. These trips could substantially degrade the existing ambient noise environment.

Thus, the traffic noise impacts from the "Land" and "Water" portion project and related projects, taken together, are cumulatively significant. Construction of sound walls and other noise-attenuating features (e.g., berms, dual-pane windows) throughout the region would require a regional program (which does not exist) and may not be feasible to implement. Because it is considered infeasible to sufficiently reduce noise at every existing and proposed sensitive receptor that would be affected, this cumulative traffic noise impact is significant and unavoidable, and the project's incremental contribution to the significant cumulative impact is itself cumulatively considerable (i.e., significant and unavoidable).

Compatibility of Sensitive Land Uses with the Ambient Noise Environment

After consideration has been made of the project-related increase in the ambient noise level (discussed in the preceding paragraph), this analysis considers whether the total noise level with project implementation would be within the allowable exterior local jurisdictional noise element standard. Any total noise level above the local jurisdictional noise element standard would be considered a significant impact.

Ambient noise levels in the general area of the aforementioned related projects would be influenced largely by vehicle traffic on nearby roadways. Table 4-8 summarizes the modeled traffic noise levels on area roadways at the approximate road corridor boundary under future no project conditions including quarry-related activities. As shown in Table 4-8, when considering traffic noise levels associated with the related projects including quarry-related activities, modeled noise levels exceed 60 L_{dn}/CNEL (which is the level considered acceptable in the applicable standards for sensitive uses) by as much as 20 dB, which could result in incompatibilities with existing sensitive uses and/or those proposed as part of the related projects (e.g., Easton and Carson Creek). Therefore, a significant impact could occur from the related projects from land use incompatibility with vehicle traffic. The 60-dB L_{dn}/CNEL noise contours for adjacent roadways (i.e., U.S. 50, White Rock Road, and Prairie City Road) with the inclusion of projected quarry truck trips completely encompass the SPA. Even considering that a typical 6-foot sound wall would reduce noise levels from approximately 5-6 dB and for each additional foot of wall another 1 dB (Caltrans 1998), and incorporating the maximum setback distance feasible, noise levels would still exceed applicable standards at those sensitive uses proposed as part of the project. Thus, the incremental contribution of the "Land" portion of the project to this significant cumulative impact would be cumulatively considerable.

Based on the analyses of operational noise impacts from the "Water" portion of the project, minimal noise from vehicular traffic would be expected from the Off-Site Water Facilities WTP. However, the proximity of pump and generator facilities for the Off-Site Water Facilities pumping facilities, and the WTP, to adjacent sensitive receptors is not known at this time and, therefore, the City is unable to confirm whether enclosing pump and generator facilities at the booster pump station and well sites would mitigate water-related operational noise to a less-than-significant level. Although unlikely, in order to be conservative, this analysis assumes that pumping and WTP operations, when considered in combination with the related projects, could, at times, be in excess of Sacramento County and City of Rancho Cordova standards. Therefore, the incremental contribution of the "Water" portion of the project to this significant cumulative impact could be cumulatively considerable.

Cumulative Mitigation Measure Noise-1-Land: Implement Measures to Reduce Exposure of Sensitive Receptors to Increased Traffic Noise Levels from Quarry Truck Traffic.

The City of Folsom does not have direct jurisdiction over the Teichert, DeSilva Gates, or Walltown quarry project applicants as these projects are located within the unincorporated portion of the County of Sacramento. The City's authority to control the activities of the quarry trucks includes restrictions or actions that would be applicable within the City's jurisdictional boundaries. For example, the City could

designate truck routes through the City consistent with California Vehicle Code section 21101(c), including truck routes in the Folsom South of U.S. 50 project area, so as to prohibit or limit quarry trucks' use of City roads adjacent to areas where projected truck traffic volumes would otherwise result in exposure of sensitive receptors to operational noise from quarry truck traffic and/or traffic safety hazards. If this approach is selected by the City, then prior to the approval of the first tentative subdivision map or any other discretionary approval that would place sensitive receptors along any roads the quarry trucks could use to access U.S. 50, the City's traffic department and consultants shall analyze and propose to the City Council for approval designated truck routes from the quarries through City jurisdiction to access U.S. 50 that would allow a level of truck traffic that would avoid any potentially significant impact on sensitive receptors from truck traffic noise within the Folsom South of U.S. 50 project area, as well as any other existing or planned uses that would contain sensitive receptors, so as to ensure that sensitive receptors are not exposed to interior noise levels in excess of 45 dBA, or increases in interior noise levels of 3 dBA or more, whichever is more restrictive.

As an alternative to designating truck routes, the following measures could be voluntarily implemented by the quarry project applicant(s) (Granite [Walltown], Teichert, and DeSilva Gates) to reduce exposure of new sensitive receptors developed in the SPA to increases in traffic noise levels generated by quarry truck traffic, and are encouraged.

- The quarry project applicant(s) should meet with the City of Folsom to discuss mitigation strategies, implementation, and cost.

- A site-specific, project-level screening analysis should be conducted by the City of Folsom and funded by the quarry truck applicant(s) for all proposed sensitive receptors (e.g., residences, schools) in the SPA that would be located along the sides of roadway segments that are identified in Table 4-8 as being potentially significant under any of the analyzed scenarios. The analysis should be conducted using an approved three dimensional traffic noise modeling program (i.e., TNM or SoundPlan). Each project-level analysis should be performed according to the standards set forth by the City of Folsom for the purpose of disclosure to the public and decision makers. The project-level analysis should account for the location of the receptors relative to the roadway, their distance from the roadway, and the projected future traffic volume for the year 2030 (including the percentage of heavy trucks). If the incremental increase in traffic noise levels are determined to exceed the threshold of significance recommended by the City of Folsom, then design mitigation should be employed, which may include the following:

    - Model the benefits of soundwalls (berm/wall combination) along the quarry truck hauling roadways and affected receptors not to exceed a total height of eight feet (two-foot berm and six-foot concrete mason wall). If this mitigation measure is determined by the City of Folsom to be inadequate, additional three dimensional traffic noise modeling should be conducted with the inclusion of rubberized asphalt at the expense of the quarry truck applicant(s). No quarry trucks should be allowed to pass on any roadway segment immediately adjacent to or within the SPA until said mitigation has been agreed upon by the City of Folsom and fees for construction of said mitigation are paid by the quarry truck applicant(s).

    - Implement the installation of rubberized asphalt (quiet pavement) on roadway segments adjacent to sensitive receptors that carry quarry trucks if soundwalls do not provide adequate reduction of traffic noise levels. The inclusion of rubberized asphalt would provide an additional 3 to 5 dB of traffic noise reduction. The cost of construction using rubberized asphalt should be borne by the quarry truck applicant(s). Said mitigation fee should be determined in consultation with the quarry project applicant(s), the Folsom South of 50 Specific Plan project applicant(s), and the City of Folsom. No quarry trucks should be allowed to pass on any roadway segment immediately adjacent to or within the SPA until said mitigation fees are paid.

- To improve the indoor noise levels at affected receptors, implement the following measures before the occupancy of the affected residences and schools:

  – Conduct an interior noise analysis once detailed construction plans of residences adjacent to affected roadways are available to determine the required window package at second and third floor receptors to achieve the interior noise level standard of 45 dB L_{dn} without quarry trucks.

  – Determine the interior quarry truck traffic noise level increases at second and third floor receptors adjacent to affected roadways compared to no quarry truck conditions. Window package upgrades are expected to be necessary due to the traffic noise level increases caused by quarry trucks along affected roadways. Quarry truck applicant(s) should pay for the cost of window package upgrades (increased sound transmission class rated windows) required to achieve the interior noise level standard of 45 dB L_{dn} with the inclusion of quarry truck traffic.

Implementation: The project applicant(s) of the Folsom South of 50 Specific Plan project.

Timing: Prior to approval of first tentative map or discretionary approval within SPA that would place sensitive receptors along roadways that quarry trucks would reasonably use to access U.S. Highway 50.

Enforcement: City of Folsom Community Development Department.

Implementation of Cumulative Mitigation Measure Noise-1-Land would reduce the significant impact related to exposure of project-generated sensitive receptors to noise from increased traffic levels generated by quarry truck trips to a less-than-significant level because the City would either designate truck routes that would limit or prohibit truck traffic adjacent to sensitive receptors or the City would be able to reach a voluntary agreement with the quarry applicants that would require a site-specific noise assessment to be performed using an approved three dimensional traffic noise modeling program, and in the event the quarry trucks are shown to cause a 3 dBA increase in sound levels (or to increase interior sound levels above 45 dBA) within 400 feet of any project-generated sensitive receptors, either the setback distances of the sensitive receptors from the road would be increased, the sound wall heights would be increased, additional sound reduction measures such as quiet pavement would be constructed, or fewer quarry trucks would be allowed to pass on the roadways within 400 feet of the sensitive receptors such a 3 dBA increase would not occur. However, the City of Folsom does not have direct jurisdiction over the Teichert, DeSilva Gates, or Walltown quarry project applicants and operations; therefore, if the quarry project applicants decline to voluntarily implement the recommended mitigation, the City may adopt truck route restrictions, thereby reducing the impact to a less than significant level.

PARKS AND RECREATION

Regional recreational facilities are located near the SPA, including Bass Lake in El Dorado County and Folsom Lake, Lake Natoma, the Powerhouse State Historic Park, the Prairie City State Vehicular Recreation Area (OHV Park), and the American River Parkway in Sacramento County. Neighborhood and community parks are located throughout Sacramento and El Dorado Counties. The City of Folsom provides and maintains a full range of recreational activities and park facilities.

Implementation of the "Land" portion of the project would generate demand for parks and recreational facilities. Table A3.12-1, in Section 3A.12, "Parks and Recreation - Land," summarizes park facilities and total acreage and developed acreage of parkland in the City. A total of 385.35 acres of parkland are currently located within the City of Folsom (City of Folsom 2008). Currently, the City's parkland acreage to population ratio is currently 5.3 acres per 1,000, which is slightly above the City's park acreage standard of 5 acres per 1,000 residents. As shown

on Table 3A.12-3, in Section 3A.12, "Parks and Recreation - Land," between 84.8 and 170.0 acres of developed parks and active recreation areas would be created depending on the alternative chosen for development. All of the "Land" alternatives would meet the City's requirement of 5 acres of parkland per 1,000 residents thereby providing sufficient park facilities to meet the demand generated by the projected population at buildout. Therefore, while the related projects may result in a cumulatively considerable impact, the "Land" portion of the project would not contribute to such an impact. For the proposed GPA, existing Parks and Recreation planning in the City of Folsom has considered the growth which could occur in Multi-family Density and Multi-family High Density areas under the existing Folsom General Plan. Only the excess units (951 in total) which would be permitted under the increased density maximums are not accounted for in local park planning. The City of Folsom has an existing park surplus, with approximately 5.3 acres per 1,000 residents. Addition of 951 excess residents would lower this ratio to approximately 5.2 acres per 1,000 residents, still a surplus of park land.

In addition to the on-site facilities, the new residents would also be expected to use existing off-site recreational facilities such as those at Folsom Lake State Recreational Area, Folsom Powerhouse State Historic Park, the Prairie City OHV Park, Bass Lake, and the American River Parkway, including bicycle trails, campgrounds, boat launch facilities, and sports parks. Additional use of facilities could cause the potential physical deterioration of existing off-site local and regional park facilities. Although it cannot be fully ascertained with any degree of certainty exactly how many residents and with what frequency they would choose to use off-site recreational facilities, for purposes of this analysis, it is assumed that revenues from use charges and admission fees of these off-site facilities would increase along with increased usage, thus supporting increased maintenance. Similarly, increases in use from the related projects would be expected to result in an increase in admission revenues for park maintenance. As a result, the "Land" portion of the project, the proposed GPA, and related projects would not contribute to physical deterioration of regional park facilities, and the project would not result in a cumulatively considerable incremental contribution to a significant cumulative impact related to regional park facilities.

Within the Off-site Water Facilities Study Area, the Sacramento River provides water-dependent activities, such as boating and fishing, and recreational activities including camping, hiking, picnicking, and sightseeing. Implementation of the "Water" portion of the project would result in very minor changes in flows within the Sacramento River. These changes are generally attributed to changes in the surface water delivery schedule and quantity of return flow back to the Sacramento River. As discussed in Section 3B.12, "Parks and Recreation - Water," this operational change would result in a negligible change in the frequency with which flows in the Sacramento River are within a range suitable for water-dependent recreation during the peak recreation season (May to September). Therefore, the "Water" portion of the project would not result in a cumulatively considerable incremental contribution to a significant cumulative impact related to water-dependant recreational opportunities.

POPULATION, EMPLOYMENT, AND HOUSING

Depending on the action alternative chosen for development, implementation of the "Land" portion of the project would include an estimated population of 16,761–24,335 new residents at full buildout. As discussed in Section 3A.13, "Population, Employment, and Housing - Land," it cannot be determined whether the "Land" portion of the project would generate population growth that exceeds estimates for Folsom or Sacramento County under their currently adopted General Plans, and the "Land" portion of the project could potentially result in unplanned population growth in the area. Population growth, by itself, is not considered a significant cumulative effect because it is not an environmental impact. However, the direct and indirect effects, such as housing and infrastructure needs that are related to population growth, can lead to physical environmental effects, the impacts of which are considered throughout Chapter 3 of this EIR/EIS.

The "Water" portion of the project would not involve construction of new housing that would directly result long-term increases in population. Therefore, the "Water" portion of the project would have no impacts related directly to population growth and no cumulatively considerable impacts would occur.

The proposed GPA could result in an excess of 532 units within the current City boundaries beyond those incorporated in the currently adopted Folsom General Plan. Population growth, by itself, is not considered a significant cumulative effect because it is not an environmental impact. However, the direct and indirect effects, such as housing and infrastructure needs that are related to population growth, can lead to physical environmental effects, the impacts of which are considered in Section 3A.10, "Land Use and Agricultural Resource – Land," throughout Chapter 3 of this EIR/EIS, and in the City's General Plan EIR.

Jobs/Housing Balance

The concept of jobs/housing balance presumes that the environment and quality of life in a given area benefit when the area has a balance between its housing supply and its employment base. In the broadest sense, the balance of jobs and housing in a metropolitan region is defined as provision of an adequate supply of housing to house workers employed in a defined geographic area, such as a community, a city, or other subregion. Alternatively, a jobs/housing balance can be defined as adequate provision of employment in a defined area that generates enough local workers to fill the housing supply. The opportunity to live close to the workplace afforded by providing housing close to jobs should translate to lower congestion and commute times by eliminating the necessity for long-distance commutes. It also provides increased opportunities to use transit, bike, or walk to work in lieu of driving. An area that has too many jobs relative to its housing supply is likely (in the absence of offsetting factors) to experience substantial in-commuting, relatively rapid increases in housing prices, and intensified pressure for additional residential development. Conversely, if an area has relatively few jobs in comparison to the number of employed residents, many of the workers are required to commute to jobs outside their area of residence. Commuting results in more traffic congestion, air quality degradation, and noise generation.

The simplest measure of jobs/housing balance is an index based on the ratio of employed residents (which is influenced by the number of homes) to jobs in the area. An index of 1.0 indicates that the supply of jobs and housing are balanced. An index above 1.0 indicates that employment growth is outpacing housing growth and, therefore, there are more jobs than employed residents, and may suggest that many employees are commuting in from outside the community. An index below 1.0 indicates that housing growth is outpacing employment growth and, therefore, there are more employed residents than jobs and may suggest that many residents are commuting to jobs outside the community. Imbalance is often a result of local land use policy; therefore, long-term job uses and housing in an urban area should eventually equalize with good planning practices, and thus reduce commuting.

Jobs/housing indices are more useful for examining the potential for "self-containment" at the regional level than for determining whether this self-sufficiency actually exists in a given community. Balance involves more than matching numbers of housing units and numbers of jobs. Even if communities have a statistical balance between jobs and housing, they are still very likely to experience in-commuting and out-commuting, given the variety and dispersed nature of employment and residential opportunities elsewhere in the region and the high level of mobility offered by automobiles. Trip-making decisions, including the choice of mode, are based on many factors. In the most rational scenario, mode choice is based on the relative time, cost, and availability of alternative transportation modes. However, mode choice is not simply the result of a rational decision between equally weighed travel tradeoffs. Based on theory and empirical research, the perceived cost, household characteristics, and land use also affect mode choice. Additional factors shape the context in which people make trip decisions, including the fact that two-income households usually work in different locations; frequent job turnover reduces the ability to locate with reference to one's workplace; and factors other than jobs access, such as quality of schools, housing prices, and access to other amenities, influence residential location choices as much as or more than proximity to employment. (Atlanta Regional Commission 2002.)

Because the "Land" portion of the project would provide employment opportunities in Sacramento County, including the City of Folsom, as well as the greater Sacramento region, and would be located on the El Dorado County line with off-site improvements being constructed in El Dorado County, the geographic area is defined as

El Dorado and Sacramento Counties. To allow for consistency in comparisons, the jobs/housing balance indices in this analysis were calculated using the SACOG Metropolitan Transportation Plan's (MTP's) estimated housing and employment projections for these counties. These projections were based on employment, population and housing growth in specific geographic locations using recent growth trends; planned projects (both adopted and in-process) in each jurisdiction; planning-related issues such as flood control, habitat and infrastructure; and the long-range planning projects in each location. The jobs/housing indices were determined by dividing the projected number of jobs by the projected number of housing units. (SACOG 2007:15-1.)

The ratio of jobs to housing varies considerably in Sacramento County. Rancho Cordova had the highest jobs ratio in 2005 with a jobs/housing index of 2.70, followed by the Cities of Sacramento and Folsom with jobs/housing indices of 1.99 and 1.29, respectively. Citrus Heights had the lowest jobs to housing ratio in 2005 with a jobs/housing index of 0.53. As a whole, the jobs/housing index for Sacramento County was 1.34 in 2005. Over the next 25 years, job growth is expected to improve the number of jobs compared to the number of employed residents living in the county and the jobs/housing index is projected to decrease in Sacramento County to 1.21 in 2035. (SACOG 2007:15-3.)

El Dorado County has maintained a low ratio of jobs-to-housing units. In 2005, the jobs/housing index for El Dorado County was 0.79. The majority of the county's employment growth has occurred in the unincorporated communities of El Dorado Hills and Cameron Park at the western edge of the county. These areas have experienced robust residential growth due to entitlement of several specific plans. Apart from additional commercial and industrial growth along U.S. 50, El Dorado Hills will continue to function as El Dorado County's main jobs center. Employment growth in the county is expected bring the jobs/housing index for El Dorado County to 0.98. (SACOG 2007:15-2, 15-3.)

The estimated number of jobs generated by the "Land" portion of the project and the number of employable residents in the SPA would depend on the project (action) alternative chosen for development. The jobs/housing index would be 1.2 for the Proposed Project Alternative, 1.3 for the Resource Impact Minimization Alternative, 1.5 for the Centralized Development Alternative, 1.1 for the Reduced Hillside Development Alternative, or 1.8 for the No Federal Action Alternative, which indicates that the project would be job rich regardless of the alternative implemented. The jobs/housing index for Folsom was 1.29 in 2005, and is projected to decrease to 1.23 in 2035, which indicates the city would remain job rich (SACOG 2007:15-2). Therefore, the project would cumulatively affect the city's jobs-housing balance.

At a more regional level, the jobs/housing index for Sacramento County was 1.34 in 2005 and is projected to decrease to 1.21 in 2035. Overall, the jobs/housing index for the Sacramento region (Sacramento, El Dorado, Placer, Sutter, Yolo, and Yuba Counties) as a whole was 1.24 in 2005 and is projected to decrease to 1.15 by 2035. The jobs/housing indices for these counties indicate that planned housing projects, including this project, are expected to provide housing opportunities and improve the current jobs/housing balance to approximately 1.15 jobs to one housing unit by 2035; however, the Sacramento region would remain slightly job rich. In this respect, the project would cumulatively affect the county and Sacramento region jobs-housing balance. (SACOG 2007:15-2.)

The jobs/housing index prepared for the "Land" portion of the project is not applicable to the No Project Alternative because the No Project Alternative consists of development of only 44 rural residences scattered over 3,500 acres. Therefore, the No Project Alternative would have a negligible effect on the jobs/housing balance .

PUBLIC SERVICES

In terms of cumulative impacts, the appropriate service providers are responsible for ensuring adequate provision of public services within their jurisdictional boundaries. As indicated in Section A3.14, "Public Services," public services would be provided to the SPA by the City of Folsom Fire Department, the City of Folsom Police Department, and the Folsom-Cordova Unified School District (FCUSD). The related projects within the City of

Folsom would use these same service providers. Related projects outside the City of Folsom would rely on different service providers, within Sacramento and El Dorado Counties. Significant impacts of the project analyzed in the EIR/EIS associated with the potential to impede the provision of emergency services during construction, increase demand for fire protection services and facilities, and adequate water pressure for fire flow would be reduced to less-than-significant levels through implementation of the mitigation measures identified in Chapter 3A.14, "Public Services - Land."

Future development in the City of Folsom would increase the demand for public services. In terms of cumulative impacts, appropriate service providers are responsible for ensuring adequate provision of public services within their jurisdictional boundaries. At this time, it is unknown whether sufficient police, fire, school facilities and other public services are planned to serve the related projects. While some of the related projects include proposals for the construction of service facilities, including schools, others do not. However, it is clear that sufficient police facilities, fire stations, and schools would need to be constructed to serve the related projects.

For the "Land" portion of this project, proposed on-site elementary and high schools would have sufficient capacity to accommodate students living in the SPA. In addition, these elementary and high school facilities would potentially have capacity for some additional students generated by related projects. Proposed on-site middle school facilities would have sufficient capacity to accommodate students generated under the Resource Impact Minimization, Centralized Development, and No Federal Action Alternatives. However, under the Proposed Project and Reduced Hillside Development Alternatives, the middle school would not accommodate all students, resulting in a shortfall of school services. The Proposed Project and Reduced Hillside Development Alternatives could potentially result in a significant cumulative environmental effect associated with the development of new school facilities. California Government Code Section 65996 provides that payment of school impact fees constitutes adequate CEQA mitigation for all project-specific and cumulative effects relating to adequacy of school facilities as a result of residential development.

Although a cumulative shortage of public services and facilities would not represent in itself a significant environmental impact under CEQA because these are not physical impacts on the environment, such a shortage would lead to the need to develop additional public-services facilities, which could in turn lead to significant construction- and operation-related physical impacts on the environment. It is assumed that the development of the related projects, and development of the additional public-services facilities required to serve them, would be preceded by the required CEQA review. However, conducting the required CEQA review of the related projects would not necessarily guarantee that significant environmental effects associated with construction of new fire, police, school facilities, and other public services would not occur. Hence, significant cumulative environmental indirect impacts associated with the development of new fire, police, school facilities, and other public services associated with the related projects could result in a cumulatively considerable impact.

At this time, it is unknown whether sufficient police, fire, school facilities and other public services are planned to serve the additional residential units which could be built under the proposed GPA. Implementation of existing City regulations and mitigation measures proposed in Section 3A.14, "Public Services - Land," would reduce these impacts to a less-than-significant level, but could require construction of new or expanded facilities to serve the new population, potentially resulting in a considerable contribution to a cumulatively significant impact.

Measure W would require the project applicant(s) to fund and construct fire, police, and school facilities in the SPA without reducing current service levels in the City. With payment of the state-mandated school impact fees, implementation of the "Land" portion of the project would also have a less-than-significant impact on school services and facilities. Therefore, the implementation of the "Land" portion of the project would not result in cumulatively considerable incremental contribution to a significant cumulative impact related to the development of necessary public services facilities.

Implementation of the "Water" portion of the project would allow the City to provide water service to new development within the SPA, including water service for fire protection, public safety, and educational activities.

Therefore, the "Water" portion of the project would have no impacts related to increased demand for public services and no cumulatively considerable impacts would occur.

TRAFFIC AND TRANSPORTATION

For traffic and transportation analysis purposes, cumulative conditions reflect year 2030 conditions, the anticipated build-out date of the SPA, and include the increased population that would be generated by the proposed GPA. Land use for the cumulative scenarios is based on the following sources: SACOG forecasts; the City of Folsom General Plan; the City of Rancho Cordova General Plan; the El Dorado County General Plan; the proposed Easton/Glenborough Specific Plan; the Cordova Hills area unapproved Phase I plan; and the proposed Teichert, Walltown, and DeSilva-Gates quarries south of the site. The cumulative traffic volume increases would result in unacceptable levels of service at various roadway segments, intersections, and freeway ramps in the study area as detailed in Section 3A.15, "Traffic and Transportation - Land," of this EIR/EIS. Furthermore, many of the identified impacts would occur outside of the City's jurisdiction and therefore the City cannot impose or enforce mitigation; however, it is expected that these impacts would be reduced to a less-than-significant level if the respective agencies, i.e., Caltrans, Sacramento County, El Dorado County, imposed and enforced specific mitigation measures. Buildout of the "Land" project, in conjunction with other planned, proposed, and approved projects in the vicinity, would result in cumulatively considerable increases to peak-hour and daily traffic volumes, even if the other agencies cooperated to implement mitigation measures.

Construction of the "Water" portion of the project would generate temporary and short-term and intermittent reductions of roadway capacities associated with the movement of construction equipment. Related projects within the Off-site Water Facilities Study Area include roadway improvement projects such as the White Rock Road Realignment and Widening Project, the Florin Road Widening Project, and the Capital Southeast Connector Project. Mitigation in Section 3B.15, "Traffic and Transportation - Water," would reduce the potential for traffic disruptions and temporary delays to a less-than-significant level through preparation of a traffic control plan. Over the long-term, operation of the "Water" portion of the project could generate a minimal number of new vehicle trips from employees traveling to and from the White Rock or Folsom Boulevard WTP and routine maintenance and inspection activities of the conveyance pipeline and booster pump station. Therefore, the "Water" portion of the project would not result in a cumulatively considerable incremental contribution to a significant cumulative impact related to long-term increased traffic on local or regional roadways.

UTILITIES AND SERVICE SYSTEMS

Future development in Sacramento and El Dorado Counties would increase the demand for utilities in the region. In terms of cumulative impacts, the appropriate service providers are responsible for ensuring adequate provision of public utilities within their jurisdictional boundaries. As indicated in Sections 3A.16 and 3B.16, "Utilities and Service Systems," the necessary public utilities would be provided to the SPA by the City, SRCSD, EID, Sacramento Metropolitan Utility District (SMUD), Pacific Gas & Electric Company (PG&E), AT&T, and Comcast. Public utilities would be provided to the "Water" portion of the project by SMUD and AT&T. The related "Land" projects within the Cities of Folsom and Rancho Cordova would rely on similar service providers (with the exception of EID). Related projects outside the Cities of Folsom and Rancho Cordova would rely on a variety of service providers, within Sacramento and El Dorado Counties, some of which could include SRCSD, EID, PG&E, AT&T, and Comcast. The "Land" portion and "Water" portions of the project and the proposed GPA would result in less-than-significant impacts associated with increased demand for electrical and communications services and infrastructure, and the "Land" portion of the project would result in less-than-significant impacts associated with increased demand for SRCSD off-site wastewater collection and conveyance facilities; increased generation of solid waste; and increased demand for natural gas and cable television services and infrastructure. Tables 3A.16-3, 3A.16-4, and 3A.16-5 in Section 3A.16, "Utilities and Service Systems - Land," summarize wastewater generation, solid waste generation, and electrical and natural gas service demands, respectively.

Water Supply

Presently, there are no public water supply facilities in the SPA. Implementation of the "Water" portion of the project would allow the City to provide water service to new development within the SPA. The "Water" portion of the project proposes to acquire not more than 8,000 AFY of CVP settlement supply water from the NCMWC to meet the water supply demands at buildout of the "Land" portion of the project. That water would be permanently assigned to the City and this water supply would be provided by Reclamation for diversion from the Sacramento River.

In compliance with SB 610, the City has prepared a water supply assessment (WSA) to evaluate the adequacy of existing and future water supplies to meet the water demand created by the "Land" portion of the project in conjunction with existing and future development (Appendix M1). The WSA concluded that NCMWC would have sufficient surface water supplies to serve the "Land" portion of the project.

Water Conveyance and Treatment Facilities

Presently, there are no public water supply facilities in the SPA. A new on-site water system would be constructed and would include transmission and distribution pipelines, aboveground water storage tanks, and booster pump stations. The on-site water system would be incrementally expanded to meet the demands of the "Land" portion of the project.

The "Water" portion of the project would construct off-site water conveyance and treatment facilities to convey water to the SPA. These off-site facilities consist of (1) a point of diversion on the Sacramento River at the Freeport Project, (2) a raw or treated-water booster pump station, and (3) a raw or treated-water transmission pipeline to convey the water to the SPA. The point of diversion, booster pump station, and water transmission pipeline would be sized to accommodate not more than 6,000 AFY of water purchased from NCMWC. Water treatment would be provided through the Vineyard WTP or construction of the White Rock WTP or Folsom Boulevard WTP. The WTP alternatives would have an ultimate capacity of approximately 10 million gallons per day (mgd).

Implementation of mitigation measures in Sections 3A.16 and 3B.16, "Utilities and Service Systems," would reduce potentially significant project-related impacts related to on- and off-site water conveyance facilities to a less-than-significant level by ensuring that sufficient on- and off-site water conveyance infrastructure and facilities would be available to serve all "Land" portions of the project. Therefore, the "Land" and "Water" portions of the project would not result in a cumulatively considerable incremental contribution to a significant cumulative impact related to water conveyance and treatment facilities.

WASTEWATER CONVEYANCE FACILITIES

The SPA is presently not served by any municipal wastewater collection and treatment systems. Approximately 3,313 acres of the SPA west of Empire Ranch Road is within the SRCSD service area and the remaining 189 acres east of Empire Ranch Road is within both the SRCSD and EID service areas.

A draft sewer master plan was prepared for the project to address the viability of providing sewer service to the SPA and identify on- and off-site facility needs and design. Proposed on-site wastewater collection trunk lines and all other planned elements of the wastewater system would be sized to accommodate planned wastewater flows.

The proposed GPA could result in construction of 546 units beyond those envisioned in the existing Folsom General Plan. In combination with future projects that may be built within the City of Folsom, the proposed GPA could contribute considerably to a potentially significant cumulative impact related to wastewater conveyance. Mitigation Measures 3A.16-1 and 3A.16-3 would require proof of capacity prior to approval of development under the proposed GPA, and would also result in a less than considerable cumulative contribution.

Sacramento Regional County Sanitation District

The wastewater generated within the 3,313-acre SRCSD service area would ultimately be conveyed to the Folsom South Pump Station that is north of Easton Valley Parkway and approximately 1,500 feet west of Oak Avenue. From the Folsom South Pump Station, the proponents of the Folsom South of U.S. 50 Specific Plan would construct an off-site force main to convey flows to an existing SRCSD 24-inch force main located within Iron Point Road north of U.S. 50 and downstream of the existing Folsom East 3B Pump Station. The existing 24-inch force main is currently a dry pipeline and was constructed as part of SRCSD's Folsom East Interceptor project for future use by the "Land" portion of the project. Therefore, the "Land" portion of the project and the proposed GPA would not result in a cumulatively considerable incremental contribution to a significant cumulative impact on SRCSD wastewater conveyance facilities.

El Dorado Irrigation District

Approximately 189 acres of the SPA east of Empire Ranch Road is within the EID service area and wastewater collection and conveyance facilities for that area would be provided by EID. Sewer flows from the EID service area would be conveyed to an existing pump station at the intersection of White Rock Drive and Winterfield Drive and ultimately conveyed to the El Dorado Hills Wastewater Treatment Plant (WWTP). The existing collection and conveyance facilities may not have the capacity to accommodate wastewater flows generated by the "Land" portion of the project om the EID service area and could require improvements to meet project demands. Implementation of mitigation contained in Section 3A.16, "Utilities and Service Systems - Land," would reduce significant impacts associated with increased demand for EID conveyance facilities to a less-than-significant level because adequate wastewater conveyance facilities would be documented before approval final maps and issuance of building permits.

However, potential improvements could include expanding the capacity of existing sewer pipelines, upgrading or replacing the existing pump, and installing an additional manhole; it is not known at this time what specific improvements would be required. Any improvements to these facilities would require additional analysis in a subsequent CEQA document to identify specific impacts and any required mitigation measures. Impacts resulting from improvements to EID collection and conveyance facilities could include: temporary, short-term generation of criteria air pollutants, such as PM_{10} (e.g., respirable particulate matter with a diameter smaller than 10 microns) and emissions of ozone precursors (e.g., reactive organic gases and oxides of nitrogen) during construction; temporary lane closures; increased truck traffic and other roadway impacts during construction; exposure of sensitive receptors to noise levels above noise ordinances during construction; exposure of sensitive noise receptors to new stationary-source noise from potential pump station improvements; and exposure of construction crews and the public to hazardous materials used in construction.

Since it is unknown if existing collection and conveyance facilities have the capacity to accommodate wastewater flows generated by project development, the "Land" portion of the project could directly and indirectly contribute to the need for off-site EID wastewater facility improvements. The "Land" portion of the project would contribute to the potentially significant environmental effects associated with improvements to these facilities for which feasible mitigation may not be available to reduce impacts to a less-than-significant level.

Because future improvements to the EID collection and conveyance facilities would be required to serve the project and other development in the EID service area, the environmental impacts of these facilities are associated with development of the project. Therefore, the "Land" portion of the project and related projects could contribute to the indirect and direct significant impacts associated with the future improvements to the collection and conveyance facilities that would be needed to serve the "Land" portion of the project and the related projects. Therefore, related projects could result in cumulatively considerable (i.e., significant) impacts associated with increased demand for wastewater conveyance facilities, and the "Land" portion of the project would result in a cumulatively considerable incremental contribution to this cumulatively significant impact.

Wastewater Treatment Facilities

Sacramento Regional County Sanitation District

Depending on the project or action alternative chosen for development, approximately 3.83 to 5.76 million gallons per day (mgd) of average dry-weather flow and 8.58 to 12.10 mgd peak wet-weather flow would be generated within the SRCSD service area (MacKay & Somps 2008b; Zoller, pers. comm. 2009).

The wastewater flows generated in the SPA, including the 189-acre portion of the SPA that would be served by EID, have been planned for in the SRCSD Master Plan 2000. The master plan estimates that buildout of the SPA would generate an average dry-weather flow of 6.82 mgd and a peak wet-weather flow of 14.48 mgd (SRCSD 2003b:Table 3-1). Because 189 acres of the SPA would be served by EID, the project-related average-dry weather flow and peak-wet weather flow would be less than those identified in the SRCSD Master Plan 2000.

The *Sacramento Regional Wastewater Treatment Plant 2020 Master Plan* (2001) provides for expansion of the Sacramento Regional Water Treatment Plant (SRWTP) to 218 mgd, and provides a phased program of recommended wastewater treatment facilities and management programs to accommodate planned growth through the year 2020. According to the 2020 Master Plan EIR, the permitted capacity (181 mgd) of the SRWTP was expected to be reached before 2010. However, flows to the SRWTP have consistently decreased between 2000 and 2006 from 155 mgd to 131 mgd. The reason for reduced flows is a result of water conservation efforts over the last 10 years. In addition, State legislation passed in 2009 and the SRCSD commitment to promote water supply reliability and Delta sustainability would substantially reduce the amount of wastewater generated in the future.

The expansion of the SRWTP to 218 mgd was based on growth rates expected to be achieved in the Sacramento County region by 2020. This projected capacity does not specifically include buildout of the "Land" portion of the project or the proposed GPA. Note that the 218 mgd total does not represent a buildout population total for SRCSD; rather, it represents the amount of growth expected within SRCSD based on projections. The SRCSD has determined that growth within the district is less than what was projected in the 2020 master plan and the SRWTP can provide capacity to future development beyond what was originally anticipated. Although there is expected to be sufficient SRWTP capacity to accommodate project flows through 2020, there would be no assurances that the SRWTP would have adequate capacity for new wastewater flows for the SPA occurring after 2020. Over time, additional planning at the SRWTP would occur, and overall capacity would be assessed and additional capacity planned for and added. The SRWTP site has sufficient land area to accommodate a substantially higher flow than 218 mgd; however, SRCSD's plans beyond the next 12 years are speculative.

Because there is a relationship between the "Land" portion of the project (and the proposed GPA) and the need for expansion of the SRWTP, implementation of the "Land" portion of the project and the proposed GPA would contribute indirectly and incrementally to the related impacts. As described in the 2020 Master Plan EIR, construction and operation of the expanded SRWTP would result in several environmental impacts (including impacts on water quality, hydrology, and fisheries), most of which would be reduced to a less-than-significant level through implementation of mitigation. The only significant and unavoidable impact would be from temporary, short-term increases in NO_X during construction of SRWTP facilities. However, the adequacy of the EIR for the 2020 Master Plan is being litigated (see Section 3A.16, "Utilities and Service Sysems - Land" for additional information). In addition to the impacts identified above, there is a potential that new significant impacts to water quality or other resources could be identified if the EIR for the SRWTP is found inadequate and impacts are re-analyzed. However, it is speculative to draw any such conclusion at this point.

The "Land" portion of the project, the proposed GPA, and the related projects would contribute to the need to expand wastewater treatment capacity at the SRWTP facility identified by SRCSD in its 2020 Master Plan; therefore, the "Land" portion of the project and the proposed GPA would contribute to a cumulatively

considerable incremental contribution to a significant cumulative impact related to the short-term impact on air quality from expansion of the SRWTP identified in the 2020 Master Plan EIR.

El Dorado Irrigation District

Depending on the project or action alternative chosen for development, approximately 0.05 to 0.31 mgd of average dry-weather flow and 0.14 to 0.78 mgd of peak wet-weather flow would be generated within the EID service area (MacKay & Somps 2008b).

Currently, the design capacity of the El Dorado Hills WWTP is 3.0 mgd average dry-weather flow and 7.6 mdg peak wet-weather flow. As of 2007, the average dry weather flow is approximately 2.86 and the peak wet-weather flow is 8.04 mgd. Expansion of the WWTP is required to provide wastewater treatment capacity for land uses in El Dorado Hills as identified by the El Dorado County General Plan (2003). The treatment plant is currently being expanded to 4.0 mgd, which is anticipated to be completed in 2010. The full buildout of the treatment plant to 5.4 mgd is expected to occur by 2025.

Implementation of mitigation in Section 3A.16, "Utilities and Service Systems - Land," would reduce significant impacts associated with increased demand for wastewater treatment plant facilities from development of the Folsom South of U.S. Specific Plan to a less-than-significant level because adequate wastewater treatment facilities would be documented before approval of final maps and issuance of building permits.

However, the SPA was not included in the planned future capacity of the El Dorado Hills WWTP; therefore, this project would potentially result in increased in wastewater flows that exceed treatment plan capacity. Any improvements to the treatment plant would require additional analysis in a separate CEQA document to identify specific impacts and any required mitigation measures. Impacts resulting from improvements to the El Dorado Hills WWTP could include: temporary, short-term generation of criteria air pollutants such as PM_{10} and emissions of ozone precursors (e.g., reactive organic gases and oxides of nitrogen) during construction; generation of new odors from operation of expanded treatment plant facilities; degradation of water quality from increased discharges to Carson Creek; temporary roadway lane closures, increased truck traffic, and other roadway impacts during construction; exposure of sensitive receptors to noise levels above noise ordinances during construction; and exposure of construction crews and the public to hazardous materials used in construction.

It is unknown if the existing El Dorado Hills WWTP has the capacity to accommodate wastewater flows generated by development of the EID portion of the SPA, and whether the "Land" portion of the project could directly and indirectly contribute to the need for El Dorado Hills WWTP improvements. Therefore, the "Land" portion of the project could contribute to the potentially significant environmental effects associated with improvements to treatment plant facilities for which feasible mitigation may not be available to reduce impacts to a less-than-significant level.

Because future improvements to the EID WWTP would be needed to serve the "Land" portion of the project and other developments in the EID service area, the environmental impacts of these facilities would be associated with development of the "Land" portion of the project. Therefore, the "Land" portion of the project and related projects could contribute to the indirect and direct significant impacts associated with the future improvements to the EID WWTP that would be needed to serve the project and the related projects. Therefore, related projects could result in cumulatively considerable (i.e., significant) impacts associated with increased demand for wastewater conveyance facilities, and the project would result in a cumulatively considerable incremental contribution to this cumulatively significant impact.

Solid Waste

Operation of the "Land" portion of the project and the proposed GPA would incrementally increase generation of solid waste throughout buildout in the year 2030. Depending on the project (action) alternative chosen for development, approximately 67.3 to 113.9 tons per day (tpd) of solid waste would be generated for disposal at

Kiefer Landfill. The landfill is permitted to accept 10,800 maximum tpd of solid waste; however, the average intake is only approximately 6,000 tpd. The landfill is permitted to accept a maximum of 10,800 tpd of solid waste. The Kiefer Landfill receives over 700,000 tons of waste per year (Sacramento County 2009a:4-2). The landfill has a total capacity of 117 million cubic yards, and a remaining capacity of 113 million cubic yards. Currently, the landfill has a closure date of 2064. (California Integrated Waste Management Board [CIWMB] 2008.) The project-related impact from increased generation of solid waste is less than significant. Because Kiefer Landfill would have adequate capacity to serve the "Land" portion of the project, the GPA and other development in its service area, implementation of the "Land" portion of the project, the GPA, and the related projects would not result in a cumulatively considerable incremental contribution to a significant cumulative impact related to solid waste.

Electricity

SMUD is the electrical service provider for Folsom and would provide electrical service for the "Land" and "Water" portions of the project. Depending on the project alternative chosen for development under the "Land" portion of the project, the project would increase electrical demand in the SMUD service area by an average of 35.7 to 55.5 megavolt amperes (MVA) with a peak demand of 75.9 to 118.7 MVA (Capitol Utilities Specialists 2009:4). SMUD concurs with this assessment; however, SMUD has calculated the worst-case scenario as increasing electrical demand by a total of 120 MVA (Capitol Utilities Specialists 2009:5; Kim, pers. comm., 2009).

The "Land" and "Water" portions of the project and cumulative development of the related projects would increase the demand for electricity within SMUD's service area. SMUD has long-term contracts with other generators to provide an additional 1,189 megawatt (MW) of electricity for distribution per day. Throughout the year, SMUD buys and sells energy and capacity on a short-term basis to meet load requirements and reduce costs. In 2007, SMUD generated approximately 10,917 million kilowatt (kW) hours of electricity within its service area (California Energy Commission [CEC] 2008a).

SMUD received approval from CEC to build the first phase of the 500-MW Cosumnes Power Plant (CPP), which provides SMUD with 1,000 MW of power to ensure SMUD's long-range plans to meet the growing power needs of Sacramento County. The gas-fired plant, which came on line in 2006, provides enough power to meet the annual needs of 450,000 single-family homes (SMUD 2006). In addition to the CPP, SMUD has the Upper American River Project, which consists of 11 reservoirs and eight powerhouses that generate enough electricity to meet nearly 15% of SMUD's customer demand. The Upper American River Project can provide approximately 1.8 billion kW hours of electricity during a normal water year, which is enough energy to power about 180,000 homes (SMUD 2009).

SMUD currently has existing capacity to serve the "Land" portion of the project and the GPA from its electrical distribution system north of U.S. 50 (Capitol Utility Specialists 2009:5). To provide service within the SPA, SMUD has determined that a minimum of three distribution substations would be required to serve the proposed development. Also, a new 69-kV overhead transmission line would be constructed along Old Placerville Road from U.S. 50 to White Rock Road. Additional overhead transmission lines may be required depending on the location of the distribution substations. SMUD has stated that it has adequate electricity supplies to support the "Land" portion of the project without affecting service to existing customers and that it would provide new electrical infrastructure (Kim, pers. comm., 2009).

For the "Water" portion of the project, the booster pump station and WTP alternatives would increase demands for electricity. Electrical distribution infrastructure exists adjacent to each of the WTP alternatives sites and any improvements and extensions required to accommodate the "Water" portion of the project would be limited to on-site locations and performed in consultation with SMUD prior to installation. Therefore, the project-related impact from increased demand for electricity supplies and infrastructure is less than significant and the "Land"

and “Water” portions of the project would not result in a cumulatively considerable incremental contribution to a significant cumulative impact related to increased demand for electrical service.

Natural Gas

PG&E is the natural gas supplier for Folsom and would provide natural gas service for the “Land” portion of the project, the proposed GPA, and related projects within its service area. Depending on the alternative chosen, natural gas demand would increase by 655.9 to 1,050.7 thousand cubic feet per hour within the PG&E service area.

The “Land” portion of the project and cumulative development of the related projects would increase the demand for natural gas. Implementation of the “Land” portion of the project would require two additional transmission mains and two natural gas regulator stations to provide service to the “Land” portion of the project at full build-out. PG&E has indicated that it currently has capacity in its system to serve the SPA and the related projects within its service area. PG&E is able to provide natural gas and associated infrastructure to the SPA and the increase in demand for natural gas would not be substantial in relation to existing natural-gas consumption in PG&E’s service area. Therefore, the project-related impact from increased demand for natural gas is less than significant and the “Land” portion of the project would not result in a cumulatively considerable incremental contribution to a significant cumulative impact related to increased demand for natural gas.

The “Water” portion of the project would not require natural gas service. Therefore, the “Water” portion of the project would have no impacts related increased demand for natural gas and no cumulatively considerable impacts would occur.

Communications and Cable Television

The “Land” and “Water” portions of the project, the proposed GPA, and cumulative development of related projects would increase the demand for communications and cable television service. AT&T would provide communications service and infrastructure to the SPA. The “Land” portion of the project would receive service from the Folsom Nimbus Wire Center and the El Dorado Wire Center. Residential service would be provided via fiber-optic cable and commercial and retail service would be provided via copper or fiber-optic cable. AT&T would be able to provide the necessary telecommunications services and infrastructure without affecting service to its existing customers.

Comcast would provide cable television service and infrastructure to the SPA. Comcast generally improves or relocates hub sites as the need arises to meet customer demand. Comcast would extend service to the SPA via existing facilities. The “Water” portion of the project would not require cable television service; therefore, the “Water” portion of the project would have no impacts related increased demand cable television and no cumulatively considerable impacts would occur.

Because AT&T and Comcast would provide communications and cable television service and associated infrastructure to the SPA, the project-related impact from increased demand for communications and cable television services is less than significant. Therefore, related projects and other development in the region are not considered to result in a cumulatively considerable impact related to communications and cable television service, and the proposed project would not result in a cumulatively considerable incremental contribution to a significant cumulative impact.

4.2 GROWTH-INDUCING IMPACTS

4.2.1 INTRODUCTION

According to the CEQA Guidelines (CCR Section 15126.2[d]), an EIR must discuss the growth-inducing impacts of a project. In other words, the EIR must examine whether a project would lead to economic or population growth or would encourage development or other activities that could result in physical impacts on the environment. Specifically, CEQA states that the EIR shall:

> [d]iscuss the ways in which the proposed project could foster economic or population growth, or the construction of additional housing, either directly or indirectly, in the surrounding environment. Included in this are projects that would remove obstacles to population growth (a major expansion of a wastewater treatment plant might, for example, allow for more construction in service areas). Increases in the population may tax existing community service facilities, requiring construction of new facilities that could cause significant environmental effects. Also, discuss the characteristics of some projects which may encourage and facilitate other activities that could significantly affect the environment, either individually or cumulatively. It must not be assumed that growth in any area is necessarily beneficial, detrimental, or of little significance to the environment.

Direct growth-inducement would result if a project involved construction of new housing. Indirect growth-inducement would result, for instance, if implementing a project resulted in any of the following:

- substantial new permanent employment opportunities (e.g., commercial, industrial, or governmental enterprises);
- a construction effort with substantial short-term employment opportunities that indirectly stimulates the need for additional housing and services to support the new temporary employment demand; or,
- removal of an obstacle to additional growth and development, such as removing a constraint on a required public utility or service (e.g., construction of a major sewer line with excess capacity through an undeveloped area) or adding development adjacent to undeveloped land.

Growth-inducement itself is not an environmental effect, but it may foreseeably lead to environmental effects. These environmental effects may include increased demand on other community and public services and infrastructure, increased traffic and noise, degradation of air or water quality, degradation or loss of plant or animal habitats, or conversion of agricultural and open space land to urban uses.

4.2.2 SUMMARY OF GROWTH PLANNED IN THE CITY OF FOLSOM GENERAL PLAN

The City of Folsom General Plan (1988) provides for physical, economic, and environmental growth of the City. The City's General Plan is oriented toward the physical development of land uses, a circulation network, and supporting public facilities and services. As a whole, the general plan is intended to retain and enhance Folsom's quality of life, separate identity, and sense of community.

The following population data for the City of Folsom are taken from City of Folsom General Plan Housing Element Background Report, adopted June 25, 2002. The population data in the City's adopted Housing Element is drawn largely from the City's 1992 Housing Element, 1990 and 2000 U.S. Census Bureau data, DOF, and SACOG. As presented in the background report, Folsom's population was anticipated to increase from 51,884 in 2000 to 74,185 in 2010, an average annual growth rate of 3.6%. As of January 1, 2009, the population of Folsom was estimated to be 71,018 (DOF 2009), indicating that growth was closely tracking projections.

The City is the process of updating its General Plan Housing Element for the planning period of January 1, 2006 to June 30, 2013. The Draft Housing Element is based on 2000 U.S. Census Bureau data, DOF data (2007), and SACOG's most recent projections released in 2007. The City's Draft Housing Element (2008) estimates the population of Folsom will grow to 69,800 in 2013 and 76,333 in 2015 (but also show that expected population levels in 2013 may have already been eclipsed). These population projections show a substantial decline in growth from what occurred between 1990 and 2008. By 2035, population is anticipated to increase to 97,485 persons. These projections do not include population that would be generated by the project or the excess 546 units which could occur under the proposed GPA.

4.2.3 GROWTH-INDUCING IMPACTS OF THE PROJECT

DENSITY OF DEVELOPMENT

The SPA is located in unincorporated Sacramento County immediately south of the Folsom city limits (see Exhibits 2-1 and 2-2 in Chapter 2, "Alternatives"). The SPA is currently designated by the Sacramento County General Plan (1993) as General Agriculture (80 acres) and General Agriculture (80 acres)/Resource Conservation Area and is zoned by the Sacramento County zoning codes as AG-80 (Agricultural, 80-acre minimum lot size), AG-20 (Agricultural, 20-acre minimum lot size), A-10 (Interim Agricultural, 10-acre minimum lot size), and SPA (Special Planning Area). As such, up to 44 rural residences could be developed under the existing Sacramento County agricultural land use and zoning classifications.

In June 2001, the Sacramento Local Agency Formation Commission (LAFCo) approved the City's sphere of influence amendment application (Resolution No. LAFC 1196), and the City's sphere of influence was expanded to include the SPA. As part of the amendment approval, LAFCo identified conditions to ensure that future annexation of the SPA would include adequate services for new development within proposed annexation areas; avoid premature conversion of agricultural resources; preserve open space; and encourage planned, logical, and orderly patterns of urban growth. (See Chapter 2, "Alternatives," for a detailed discussion of the project background and history, including the LAFCo resolution, Memorandum of Understanding, and Measure W.)

Following LAFCo's approval of the annexation, if this occurs, Sacramento County would relinquish land use planning authority to the City, and the Sacramento County General Plan would no longer apply to the annexed areas. The project would require approval of a general plan amendment by the City of Folsom designating the SPA for urban uses consistent with the Specific Plan, and the City's jurisdictional boundary would be expanded to include the SPA. These actions are proposed with the project.

Sacramento Area Council of Governments' Sacramento Region Blueprint

The SACOG Blueprint identifies the SPA as a future planned community that would accommodate the long-term needs of Folsom and contribute to the Sacramento region. The SACOG Blueprint Preferred Scenario anticipates the project would generate approximately 7,500 jobs and develop 12,000 households (City of Folsom 2007). The Blueprint's land use designation for the SPA is illustrated in Exhibit 3.10-2, in Section 3.10A, "Land Use and Agricultural Resources - Land." It should be noted that SACOG has no land use authority. SACOG makes clear that the land use designations presented on the Blueprint are conceptual and reflect general land use locations in a local area.

Depending on the alternative selected, project implementation could result in conflicts between the project and the SACOG Sacramento Region Preferred Blueprint Scenario. The Blueprint envisions a higher density of development in the SPA than proposed under the Resource Impact Minimization and No Federal Action Alternatives. Although lower density development on a particular property may reduce the levels of impacts occurring on or emanating from the property, low densities can be considered an inefficient use of finite land resources. In areas with growing populations, low-density development can push market demand for development outward toward other areas on the urban periphery, ultimately resulting in a greater overall loss of habitat, open

space, and farmland. In the long term, these alternatives would be growth inducing and could result in greater expansion of the overall regional urban areas.

Although the Proposed Project, Centralized Development, and Reduced Hillside Development Alternatives would include a greater density of residential development and exceed the jobs projections identified in the Blueprint for the SPA, these alternatives fulfill the principles of smart growth identified in the Blueprint. These alternatives would allow for a system of multimodal transportation; would provide a variety of mixed-use areas and a range of housing choices; and would emphasize compact development, quality design, and natural resource conservation. Under smart growth principles, areas that are planned for development are developed at higher than typical densities. Although these higher densities may result in greater on-site impacts on biological, cultural, open-space, and agricultural resources, the overall area of disturbance within the region is reduced in the long term as development is concentrated in particular locations. Further, higher densities make public transit more feasible, potentially taking relative pressure off highways compared with traditional automobile-dependant development. Sacramento County is experiencing demographic pressure reflecting an increasing statewide population and intrastate migration from the San Francisco Bay Area, and the City of Folsom is interested in furthering its goals and objectives of providing a mix of housing and new jobs to its residents. Smart growth principles therefore suggest that developing the site with a higher density use while avoiding wetland areas would focus market demand for development into an area near existing development, infrastructure, and services. Thus, the Proposed Project, Centralized Development, and Reduced Hillside Development Alternatives would be growth-inducing, the higher density of development would likely provide a regional environmental benefit in terms of development patterns over the long term.

ROADWAY IMPROVEMENTS

Access to the SPA would be provided by improved roads along existing roadway alignments in the project vicinity and new roads within the SPA itself. The following off-site roadway improvements would be necessary to serve the Proposed Project or the other four action alternatives, all of which would serve the project and provide access through the SPA to adjacent properties:

- improvements to the existing interchange at U.S. 50 and Prairie City Road,
- a new interchange at U.S. 50 and Oak Avenue,
- a new overcrossing of U.S. 50 at Rowberry Drive,
- improvements to the existing interchange at U.S. 50 and Scott Road/East Bidwell Street (improvements for traffic from the south only), and
- a new interchange at U.S. 50 and Empire Ranch Road.

Growth in the SPA, and as a result of other projects in Sacramento and El Dorado Counties, would result in the need for capacity improvements to existing off-site roadways, including state highways, arterial roadways, and regional intersections. SACOG's Metropolitan Transportation Plan for 2035 (MTP 2035) addresses the regional transportation needs for Sacramento, El Dorado, Placer, Sutter, Yolo, and Yuba Counties through 2035 based on land use assumptions in the Preferred Blueprint Scenario (SACOG 2007: 21-1). The 2035 MTP has several planned roadway improvements in and in the vicinity of the SPA including:

- U.S. 50 car pool lane extensions and new auxiliary lanes from El Dorado Hills to Shingle Springs interchange;
- U.S. 50 mainline widening from Silva Ranch Parkway to Empire Ranch Road interchange;

- U.S. 50 new carpool lanes from Sunrise Boulevard to downtown Sacramento and new auxiliary lanes at various locations in Sacramento;
- White Rock Road widening to four lanes from Manchester Road to El Dorado/Sacramento County line, from Latrobe Road to U.S. 50/Silva Parkway Interchange, and from Grant Line Road to Prairie City Road;
- Prairie City Road widening to four lanes from U.S. 50 to White Rock Road; and
- Oak Avenue widening to four lanes from U.S. 50 to White Road.

These improvements, which would also serve the SPA, were identified as necessary to serve existing traffic and future development anticipated in El Dorado and Sacramento Counties. Roadway improvements are considered growth-inducing because they would serve the project, would provide access through the SPA to adjacent properties, and would provide enhanced access to currently undeveloped areas that are planned for future development. Growth pressure on these lands could potentially result in the loss of agricultural land and biological habitat, the generation of additional traffic, and the creation of air quality and noise impacts.

UTILITIES AND SERVICE SYSTEMS

Stormwater Drainage

No public storm drain facilities currently serve the SPA. Development of the project would require that a new urban storm drainage management system be provided to effectively drain the site, control flooding, and provide water quality benefits. A network of conveyance pipes, inlets, manholes, and regulating structures would direct runoff flows into a network of 16 on-site detention basins and one off-site basin west of Prairie City Road, and would incorporate water quality treatment. The on-site storm system and off-site detention basin would not be sized or intended to serve any new development on lands other than the SPA and therefore would not be growth inducing.

Water Supply

The "Water" portion of the project proposes to acquire not more than 8,000 AFY of CVP contract entitlement water from the NCMWC to meet the water supply demands at buildout of the "Land" portion of the project. CVP contract entitlement water would be permanently assigned to the City and this water supply would be provided by Reclamation for diversion from the Sacramento River. The CVP contract supplies acquired by the City as part of the Offsite Water Facilities would more than satisfy demands associated with all phases of development within the SPA during normal and dry years (for information on project phasing, please refer to Section 2.3.1 in Chapter 2, "Alternatives"). This higher quantity of water is required to factor in the 25% reduction that could occur in dry years thereby reducing the quantity delivered to 6,000 AFY. This shortage provision could leave a margin of only 400 AFY between the project demand at build-out and the available surface water supply. In recognition of this surplus, which ranges from 400 AFY in dry years up to 2,000 AFY, the City intends to make these supplies available to the NCMWC for diversion for irrigation. Under the "Land" portion of the project, the normal–year and dry-year water demands are estimated to be 5,421 AFY and 5,557 AFY respectively, for the Proposed Project Alternative. Based on the demand projections, the capacity of the conveyance and treatment improvements would be sufficient to supply projected growth through 2030. However, in assuming a lower growth rate or the addition of non-potable water supplies, the 10 mgd capacity improvements could be adequate to support additional growth through a longer period, thereby outdating the planning horizon of the Folsom Specific Plan.

The City has identified water supply and associated infrastructure as a constraint to growth within the SPA. Given that the primary objectives of the "Water" portion of the project is to secure a reliable water supply for the SPA and construct the necessary conveyance and treatment improvements to meet peak water demands, the Offsite Water Facilities would remove this obstacle. With additional conservation or recycled water, this water supply acquired for the SPA could be reasonably stretched to serve areas outside the SPA beyond 2030; although no

specific development proposal has been filed with Sacramento County. In this context, the "Water" portion of the project could indirectly facilitate growth and related secondary effects beyond the SPA in future years beyond 2030. The potential secondary effects could include the following types of impacts that are analyzed programmatically for the "Land" portion of the project:

- impacts to air quality from ozone precursors, particulate matter, TACs, and GHGs;
- increases in the ambient noise environment;
- increased traffic delay and intersection congestion;
- potential land use conflicts;
- potential impacts to special-status biological resources, wetlands, and vegetation, and other sensitive communities;
- potential impacts to historical and/or archaeological resources; and
- increased demands for public services and utility infrastructure.

Based on the discussion provided above, the degree of growth accommodation offered by "Water" portion of the project is attributed to the provision of a critical public infrastructure, in the form of potable water supplies and related infrastructure. This infrastructure would serve planned development within the SPA and new projects that might be proposed in conjunction beyond the SPA in future years beyond 2030. In this context, the securing of 8,000 AFY of CVP water and constructing the necessary conveyance and treatment infrastructure could contribute to significant and unavoidable impacts associated with the secondary effects of growth inducement.

Mitigation measures conditioned on new development in the future would be speculative to infer in this EIR/EIS. In this context, even following the application of mitigation, several of these secondary effects of growth could remain significant and unavoidable. Because the Proposed Project and the other four action alternatives would also result in a surplus of water that could be used to serve other projects in future years beyond 2030, implementing the Proposed Project or any of other four action alternatives would also contribute to significant and unavoidable impacts associated with the secondary effects of growth inducement.

There are no public water supply facilities in the SPA. On-site water supply distribution facilities (including transmission and distribution pipelines, aboveground water storage tanks, booster pumps, and potentially an on-site WTP) would be constructed specifically to serve the "Land" portion of the project and would not be connected to any existing water supply system. The on-site water transmission system and WTP would be sized to accommodate project-related water demands; therefore, on-site water supply distribution facilities would not be growth inducing.

Wastewater Conveyance and Treatment Facilities

The SPA is presently not served by any municipal wastewater collection and treatment systems. Project implementation would result in increased generation of wastewater and construction of wastewater collection and conveyance facilities. The proposed on-site sewer system would be constructed specifically to serve the Project and would be sized to accommodate planned project sewer flows.

Approximately 3,313 acres of the SPA west of the planned extension of Empire Ranch Road is within the SRCSD service area, and the remaining 189 acres east of the planned extension of Empire Ranch Road is within both the SRCSD and EID service areas.

The project-generated wastewater within the 3,313-acre SRCSD service area would ultimately be conveyed to the Folsom South Pump Station north of Easton Valley Parkway and approximately 1,500 feet west of Oak Avenue. From the Folsom South Pump Station, the project would construct an off-site force main to convey flows to an existing SRCSD 24-inch force main located within Iron Point Road north of U.S. 50 and downstream of the existing Folsom East 3B Pump Station. The existing 24-inch force main is currently a dry pipeline and was constructed as part of SRCSD's Folsom East Interceptor project for future use by the project; therefore, it would not be growth-inducing.

Wastewater flows from within the SRCSD service area would ultimately be transported to SRWTP for treatment and disposal. The SRWTP receives and treats an average of 141 mgd (as of 2008) and has a permitted dry-weather flow design capacity of 181 mgd. Flows to the SRWTP would increase over time as the population in the SRCSD service area increases. According to the *Sacramento Regional Wastewater Treatment Plant 2020 Master Plan* (2020 Master Plan), the permitted capacity of the SRWTP was expected to be reached before 2010. However, the actual rate of growth in demand has substantially slowed, and flows to the SRWTP have consistently decreased between 2000 and 2008, from 155 mgd to 141 mgd. The 2020 Master Plan provides for the expansion of the SRWTP to 218 mgd based on growth rates expected to be achieved in the Sacramento County region by 2020. This flow rate does not represent a buildout population total for SRCSD; rather, it represents the amount of growth expected within the district based on projections. The SRCSD has determined that growth within the district is less than what was projected in the 2020 master plan and the SRWTP can provide capacity to future development beyond what was originally anticipated and there is no threat that permitted capacity will be reached over the next several years. Over time, additional planning at the SRWTP would occur, and overall capacity would be assessed and additional capacity planned for and added. Upgrades to the SRWTP would occur without development of the Project, are required to serve regional development, and would be needed whether or not the project is developed. Expansion of the SRWTP is planned to be phased to provide for sufficient long-term capacity for regional development. Because the SRWTP is planned to accommodate growth in the region by 2020, development in the SPA that occurs by 2020 would be accommodated by planned SRWTP capacity. The SRWTP site has sufficient land area to accommodate a substantially higher flow than 218 mgd; however, future plans beyond the next 12 years are speculative. The project and regional development would contribute to the need to expand wastewater treatment capacity at the SRWTP facility and therefore would be growth inducing.

Approximately 189 acres of the SPA east of the planned extension of Empire Ranch Road is within the EID service area and off-site wastewater collection and conveyance facilities would be provided by EID. Sewer flows from the EID service area would be conveyed to an existing pump station at the intersection of White Rock Drive and Winterfield Drive and ultimately conveyed to the El Dorado Hills WWTP. The existing collection and conveyance facilities may not have the capacity to accommodate wastewater flows generated by the Project and could require improvements to meet project demands. The EID wastewater conveyance facilities would not be sized or intended to serve any new development on lands other than the SPA and therefore would not be growth-inducing.

Currently, the design capacity of the El Dorado Hills WWTP is being expanded to provide wastewater treatment capacity for land uses in El Dorado Hills as identified by the El Dorado County General Plan (2003), to meet anticipated regulatory requirements for water quality, and to help meet recycled water demands. The treatment plant is currently being expanded to 4.0 mgd, which is anticipated to be completed in late 2010. The full buildout of the treatment plant to 5.4 mgd is expected to occur by 2025. However, the SPA was not included in the planned future capacity of the El Dorado Hills WWTP; therefore, the project would potentially result in increased in wastewater flows that exceed treatment plant capacity. Any additional improvements to the WWTP required to serve the project would not add capacity for use by any new development other than the SPA and therefore would not be growth-inducing.

CONSTRUCTION-RELATED HOUSING DEMAND

Project construction activities would occur at intervals throughout the planning horizon of the project, and the site would ultimately be built out in approximately 19 years (2011-2030). It is estimated, based on prior analyses of similar projects, that project-related construction would generate approximately 500 construction jobs during the peak construction period of each of the four phases (for information on project phasing, please refer to Section 2.3.1 in Chapter 2, "Alternatives"). A greater number of construction workers would be employed during peak construction periods (determined by market demand and overall economic conditions), while fewer construction workers would be employed during nonpeak periods.

Construction workers serving the project can be expected to come from Folsom and El Dorado Hills, and other nearby communities in Sacramento, El Dorado, and nearby counties. According to the latest labor data available from the U.S. Census Bureau (2007), it is estimated that 2,269 residents in Folsom, 54,964 residents in Sacramento County, and 850 residents in El Dorado Hills are employed in the construction industry. These existing residents in the city and counties who are employed in the construction industry would likely be sufficient to meet the demand for construction workers that would be generated by the project. Because construction workers serving the project could be expected to come from Folsom itself and from nearby communities in Sacramento County or El Dorado County, neither substantial population growth nor an increase in housing demand in the region is anticipated as a result of these jobs. Furthermore, because construction workers typically do not change residences each time they are assigned to a new construction site, it is not anticipated that there would be any substantial project-related relocation of construction workers to the immediate project area.

PUBLIC SERVICES

The project includes construction of two fire stations, one police service center, five elementary schools, and one combined middle school/high school, at different locations in the SPA. The timing of construction and staffing of each fire station and the police station would be completed in a manner that ensures that adequate levels of service are provided. Measure W would require the applicants to fund and construct fire, police, and school facilities in the SPA without reducing current service levels in the City.

Five elementary schools and one combined middle school/high school would be constructed in the SPA. The proposed on-site elementary schools and the high school would have sufficient capacity to accommodate students living in the SPA. In addition, these elementary and high school facilities would potentially have capacity for some additional students. Proposed on-site middle school facilities would have sufficient capacity to accommodate students generated under the Resource Impact Minimization, Centralized Development, and No Federal Action Alternatives. However, under the Proposed Project and Reduced Hillside Development Alternatives, the middle school would not accommodate all of the project-generated students, resulting in a shortfall of school services. However, the project applicants must comply with Measure W, and therefore the project applicants would be required to fund and construct sufficient middle school facilities to serve students generated by the Project. At project buildout, the elementary and high schools could accommodate all students generated by the Project as well as other students residing elsewhere in Folsom.

Implementing the Proposed Project or the other four action alternatives would not facilitate additional development with respect to public services (with the exception of schools) because the Proposed Project and the other four action alternatives would provide or ensure that additional public services would be available to meet project demands, and it would not create additional public service capacity in Folsom beyond what would be necessary to serve project development.

JOBS/HOUSING BALANCE

As described in Section 4.1, "Cumulative Impacts," the simplest measure of jobs/housing balance is an index based on the ratio of employed residents (which is influenced by the number of homes) to jobs in the area. An

index of 1.0 indicates a jobs/housing balance. An index above 1.0 indicates that employment growth is outpacing housing growth and, therefore, there are more jobs than employed residents, and may suggest that many employees are commuting in from outside the community. An index below 1.0 indicates that housing growth is outpacing employment growth and, therefore, there are more employed residents than jobs and may suggest that many residents are commuting to jobs outside the community. For the Proposed Project and the other four action alternatives, the jobs/housing indices were determined by dividing the projected number of jobs by the projected number of housing units.

The estimated number of jobs generated by the project and the number of employable residents in the SPA would depend on the project alternative chosen for development. The jobs/housing index would be 1.3 for the Proposed Project Alternative (13,210 jobs and 10,210 housing units), 1.2 for the Resource Impact Minimization Alternative (9,501 jobs and 7,965 housing units), 1.5 for the Centralized Development Alternative (13,575 jobs and 9,026 housing units), 1.1 for the Reduced Hillside Development Alternative (14,180 jobs and 12,995 housing units), or 1.8 for the No Federal Action Alternative (11,171 jobs and 6,373 housing units). These indices indicate that the project would be job-rich regardless of the alternative implemented, with jobs generated in excess of proposed number of housing units for each alternative.

The jobs/housing index for Folsom was 1.29 in 2005, and is projected to decrease to 1.23 in 2035. Although the city's jobs/housing index is expected to improve, the city would remain job rich (SACOG 2007:15-2). The excess jobs associated with Proposed Project and the other four action alternatives would be considered as contributing to increased housing demand in Folsom.

At a more regional level, the jobs/housing index for Sacramento County was 1.34 in 2005 and is projected to decrease to 1.21 in 2035. Overall, the jobs/housing index for the Sacramento region (El Dorado, Placer, Sacramento, Sutter, Yolo, and Yuba Counties) as a whole was 1.24 in 2005 and is projected to decrease to 1.15 by 2035. The jobs/housing indices for these counties indicate that planned housing projects, including this project, are expected to provide housing opportunities and improve the current jobs/housing balance to approximately 1.15 jobs to one housing unit by 2035; however, the Sacramento region would remain slightly job rich. If these workers could not be accommodated by housing units in the region, then new housing units beyond those anticipated in the Sacramento region would be needed to meet the housing demand generated by the proposed jobs. In this respect, implementation of the Proposed Project or the other four action alternatives would create a housing demand and would be growth inducing. (SACOG 2007:15-2.)

CONVERSION OF ADJACENT UNDEVELOPED LAND TO URBAN DEVELOPMENT

Surrounding land use designations are primarily determined by El Dorado and Sacramento Counties and the City of Folsom (see Exhibit 3A.10-2 in Section 3A.10, "Land Use and Agricultural Resources - Land"). The lands east of the SPA are located the unincorporated area of El Dorado County and are governed by the El Dorado County General Plan land use designations. These lands are currently developed in residential land uses.

Land north of the SPA is located within the existing Folsom city limits and is governed by the City of Folsom General Plan. This area consists of large residential and commercial developments, several of which are currently under construction or have been recently completed.

Lands south and west of the SPA are located in an unincorporated area regulated by the Sacramento County General Plan. Industrial land owned by Aerojet General Corporation and associated buffer lands are located to the west of Prairie City Road. The majority of these lands are designated by the Sacramento County General Plan as Industrial Extensive and zoned SPA (Special Planning Area) and are intended for future Aerojet General Corporation industrial buffer lands or are part of the Easton Specific Plan area.

Lands south of the SPA are characterized primarily by seasonal grazing land. These lands are designated by the Sacramento County General Plan as General Agriculture (80 acres) and are zoned AG-80 (Agricultural, 80-acre

minimum lot size) and SPA (Special Planning Area), which identifies areas that are intended for long-term agricultural purposes and have parcels large enough to maintain economically viable farming operations.

As the Project is developed, it would place urban development adjacent to undeveloped grazing lands south of the SPA. Historically, economic returns from urban development are typically substantially higher than continued use of undeveloped land, and encroaching urban uses typically make attractive the conversion of other undeveloped land to urban uses. Thus, it could be reasoned that implementing the Proposed Project or the other four action alternatives would place pressure on land south of the SPA to convert to urban uses. No urban development is currently proposed immediately south of the SPA. The land south of the SPA is located in a rural unincorporated portion of Sacramento County beyond the USB. The USB defines the ultimate boundary of urban development and is intended to be permanent, allowing modification only under special circumstances. These lands are not within the UPA, and it is not expected this area would receive urban levels of public infrastructure and services to support urban development. Further, because it would require Sacramento County to amend its general plan, land use designations, and zoning, such a land use conversion to urban development is not assured.

Approximately 2,493 acres of the SPA consists of agricultural lands under existing Williamson Act contracts. Project implementation would require the cancellation of one or more of these Williamson Act contracts before their expiration date because the proposed land uses would not be permitted under the existing contracts. Removing the impediment of Williamson Act contracts for urban development in the SPA could induce additional urban development south of White Rock Road, thereby potentially resulting in the cancellation of additional Williamson Act contracts on those lands. Nearby proposed projects, including the Teichert and Walltown quarries, would require cancellation of lands under Williamson Act contracts. Other land uses inconsistent with Williamson Act provisions and resulting in subsequent contract non-renewals could occur. As discussed above, future urban development would require Sacramento County to amend its general plan, land use designations, and zoning, and therefore such a land use conversion to urban development is not assured. Therefore, it would be speculative to try to predict if implementation of these projects would result in the cancellation of Williamson Act contracts.

4.2.4 SUMMARY OF GROWTH-INDUCING IMPACTS

Overall, the Proposed Project and the other four action alternatives would be growth-inducing because they would involve improving and constructing roadways, which would enhance access to currently undeveloped areas; contribute to the need to expand wastewater treatment capacity at the SRWTP facility; and could provide school capacity beyond that needed to serve the Proposed Project or the other four action alternatives. The impacts associated with this growth are discussed above.

The Resource Impact Minimization and No Federal Action Alternatives would conflict with the SACOG Sacramento Region Preferred Blueprint Scenario by developing the SPA at lower densities than anticipated in the Blueprint. Low densities can be considered an inefficient use of finite land resources and can push market demand for development outward toward other areas on the urban periphery. In the long term, these alternatives would be growth-inducing.

The Proposed Project, Centralized Development, and Reduced Hillside Development Alternatives would include a greater density of residential development and exceed the jobs projections identified in the Blueprint for the SPA. Although these higher densities may result in greater on-site impacts on biological, cultural, open-space, and agricultural resources, the overall area of disturbance within the region is reduced in the long term as development is concentrated in particular locations. Therefore, developing the site with a higher density use while avoiding on-site impacts would focus market demand for development into an area near existing development, infrastructure, and services, and the Proposed Project, Centralized Development, and Reduced Hillside Development Alternatives would be growth-inducing.

Implementing the Proposed Project or the other four action alternatives would effectively result in development of a population and employment base that is the size of a small town. These alternatives would result in a condition in which jobs exceed employable residents, potentially generating additional demand for housing in Folsom and the Sacramento region. Although the Proposed Project and the other four action alternatives include the provision of commercial and retail services, on-site services would meet only some of the needs of the project population. The additional population associated with the project would spur an increase in demand for goods and services in Folsom and the Sacramento region, which could result in additional development to satisfy this demand. In this respect, the Proposed Project and the other four action alternatives would be growth-inducing. It would be speculative, however, to try to predict exactly where any such new services would be located. The most logical assumption is that they would be located where the existing Folsom, Sacramento, and El Dorado Counties' and other surrounding communities' general plans currently anticipate them. The general plans have already undergone environmental review and any new individual projects requiring discretionary approvals would be required to undergo their own environmental review.

Implementing the Proposed Project or the other four action alternatives would result in large-scale urban development adjacent to undeveloped grazing lands south of the SPA and could potentially place pressure on these lands to convert to urban uses. As explained above, the land south of the SPA is located in a rural unincorporated portion of Sacramento County beyond the USB and UPA, and it is not expected this area would receive urban levels of public infrastructure and services to support urban development. Further, because it would require Sacramento County to amend its general plan, land use designations, and zoning, such a land use conversion to urban development is not assured.

4.3 IRREVERSIBLE AND IRRETRIEVABLE COMMITMENT OF RESOURCES

CEQA requires that irreversible and irretrievable commitment of resources be addressed for certain categories of projects, including the "[t]he adoption, amendment, or enactment of a plan, policy, or ordinance of a public agency" and any project also subject to NEPA. (State CEQA Guidelines CCR Sections 15127[a] and 15127[c].) NEPA requires that an environmental analysis include identification of "…any irreversible and irretrievable commitment of resources which would be involved in the proposed action should it be implemented." (Section 102 [42 USC Section 4332(c)].) Irreversible and irretrievable resource commitments are related to the use of nonrenewable resources and the effects that this use could have on future generations. Irreversible effects result primarily from the use or destruction of a specific resource (e.g., energy and minerals) that cannot be replaced within a reasonable time frame. Irretrievable resource commitments involve the loss in value of an affected resource that cannot be restored as a result of the action (e.g., extinction of a threatened or endangered species or the disturbance of a cultural resource).

There are several resources, both natural and built, that would be expended in the construction and operation of the "Land" and "Water" portions of the project. These resources include the building materials used in construction of the project and energy in the form of natural gas, petroleum products, and electricity consumed during construction and operation of housing and commercial land uses. Loss of these resources is considered irreversible because their reuse for some other purpose than the project would be impossible or highly unlikely. The project constitutes an irreversible and irretrievable commitment of the site as a land resource, thereby rendering land use for other purposes infeasible. Thus, except to the extent minimized by the designation of the on-site wetland preserve, the land would also be permanently lost as a habitat area. In addition, if the SPA is found to contain a source of kaolin clay, this natural resource would be lost a result of project construction, since buildout of the site with urban land uses would render the clay inaccessible.

4.4 RELATIONSHIP BETWEEN SHORT-TERM USE OF THE ENVIRONMENT AND THE MAINTENANCE AND ENHANCEMENT OF LONG-TERM PRODUCTIVITY

Effects on resources are often characterized as being short-term or long-term in duration. Impacts that occur only during construction are considered temporary. Impacts that occur over a period of 3 years or less result from short-term uses of the resources in an area most often associated with construction and up to 3 years after construction ceases. Construction can create temporary water quality effects and increases in noise, emissions, traffic, and human population that can disturb resources in an area but subside when the work is complete. Long-term effects relate to the maintenance and enhancement of long-term productivity—in particular, the consistency of the project with long-term economic, social, regional, and local planning objectives. These impacts may lead to permanent loss or degradation of resources. As required by Public Resources Code section 21001(g), the short- and long-term effects of the "Land" and "Water" portions of the project under consideration are summarized below.

4.4.1 SHORT-TERM USES

Implementation of the Proposed Project, Resource Impact Minimization, Centralized Development, Reduced Hillside Development, or No Federal Action Alternatives, and implementation of any of the "Water" alternatives, would result in temporary and short-term construction-related impacts. As discussed elsewhere in this EIR/EIS, the temporary and short-term construction impacts would be associated predominantly with water quality, traffic, air quality emissions, and noise. The project applicant(s) would implement mitigation measures identified in each topical section to reduce these impacts to a less-than-significant level wherever feasible and available. At the same time, however, construction of the project would create economic benefits during construction, in the form of jobs and the subsequent direct and indirect demand for goods and services.

Under the No Project Alternative/No Water Facilities Alternative, a total of 44 single-family dwelling units could be constructed. All or a portion of these dwelling units could be constructed by individual property owners. Construction of these individual dwelling units would require a minimal number of construction workers and subsequently would create minimal economic benefits during construction and minimal direct and indirect demand for goods and services.

4.4.2 LONG-TERM USES

Implementation of the Proposed Project, Resource Impact Minimization, Centralized Development, Reduced Hillside Development, or No Federal Action Alternatives, and implementation of the "Water" alternatives (Preferred Alternative or alternatives 1, 1A, 2, 2A, 2B, 3, 3A, or 4, 4A) would result in long-term impacts related to the loss of biological resources and habitat, open space, and cultural resources; a change in the visual character and quality of the SPA; air quality emissions; noise; increased traffic; and increased demand for public services and utilities, including water supply, wastewater service, natural gas, electricity, communications service, fire protection, police service, and public schools. However, long-term economic productivity in Folsom and the Sacramento region would be substantially enhanced through development of commercial and retail services. Long-term benefits and increases in productivity from implementation of the project are described below.

- A well-integrated, mixed-use master-planned community would be developed. A pedestrian-friendly, human-scale community environment would be developed, with a safe and pleasant place for people to live, work, and recreate.

- The project would provide employment-generating uses, including a regional commercial center, town center, and smaller neighborhoods centers, for Folsom and the surrounding Sacramento region. These uses would

result in long-term community benefits, including generation of substantial permanent employment opportunities and needed retail uses and fiscal benefits from tax-generating land uses.

- A regional commercial center would be situated along U.S. 50 and Scott Road adjacent to and just north of the mixed-use town center. This adjacency is intended to promote a relationship between this regional-scale commercial and the walkable character of the town center. Additional commercial uses would be of a larger scale and highway oriented. Commercial- and service-based uses would be incorporated into neighborhood centers and include residential elements such as separate, higher density residential buildings.

- A variety of housing types are proposed to better serve the economic diversity of local homebuyers, including single-family detached and attached homes, apartments, condominiums, and townhomes. This would help alleviate the existing and future jobs/housing imbalance in Folsom and the Sacramento region. Particular emphasis would be placed on affordability and proximity of housing to the major employment-generating centers along the U.S. 50 corridor.

- Open space, recreational uses, and parks are proposed throughout the community and integrated within its design. Approximately 30% of higher density residential uses would be located near commercial uses, parks, and schools to create walkable communities.

- A public transit corridor would be included throughout the SPA with connections to the regional commercial center, town center, and neighborhood centers. Bus transit routes would be integrated into systems provided by Folsom and Regional Transit. Multi-use trails, bicycle trails, and pedestrian walkways and sidewalks would be incorporated into the development so that people could complete trips without depending exclusively on major roads, secondary roads, or automobiles.

Under the No Project Alternative/No Water Facilities Alternative, a total of 44 single-family dwelling units could be constructed. Construction of these individual dwelling units would result in substantially fewer than the impacts associated with project development; however, there would be a significant cost to the long-term productivity and future economic and socioeconomic well-being of the area.

4.5 SIGNIFICANT AND UNAVOIDABLE ADVERSE IMPACTS

CCR Section 15216.2(b) of the State CEQA Guidelines requires EIRs to include a discussion of any significant environmental impacts that cannot be avoided if the project is implemented. Chapter 3 of this EIR/EIS provides a detailed analysis of all significant and potentially significant environmental impacts related to implementing the project; identifies feasible mitigation measures, where available, that could avoid or reduce these significant and potentially significant impacts; and presents a determination whether these mitigation measures would reduce these impacts to less-than-significant levels. Section 4.1 identifies the significant cumulative impacts resulting from the combined effects of the project and related projects. If a specific impact in either of these sections cannot be fully reduced to a less-than-significant level, it is considered a significant and unavoidable adverse impact.

As described below in Sections 4.5.1 through 4.5.14 and listed in Table 4-9, project implementation would result in significant and unavoidable adverse impacts in nine environmental issue areas. Additional significant and unavoidable impacts could occur if mitigation for off-site elements that is outside the control of the lead agencies is not implemented (see Section 4.5.15 below). Finally, the project would make a cumulatively considerable incremental contribution to significant cumulative impacts in seven environmental issue areas (see Section 4.5.16 below).

Table 4-9
Summary of Project-Related Significant and Unavoidable Impacts

Section Name/Issue Area/Project Component	Impact Number	Impact Title
Aesthetics - Land	3A.1-1	Substantial alter nation of a scenic vista
	3A.1-2	Damage to scenic resources within a designated scenic corridor
	3A.1-3	Substantial degradation of visual character
	3A.1-4	Temporary, short-term degradation of visual character for developed project land uses during construction
	3A.1-5	New skyglow effects
Air Quality - Land	3A.2-1	Generation of construction emissions of NO_X and PM_{10}
	3A.2-2	Generation of long-term operational (regional) emissions of ROG and NO_X
	3A.2-4	Exposure of sensitive receptors to short- and long-term emissions of toxic air contaminants
	3A.2-6	Possible exposure of sensitive receptors to odorous emissions
Air Quality - Water	3B.2-1	Exceed Air Quality Standards
Biological Resources - Land	3A.3-1	loss and degradation of Waters of the U.S., including wetlands, and Waters of the State
	3A.3-2	Loss and degradation of habitat for special-status wildlife species and potential direct take of individuals
	3A.3-5	Loss of blue oak woodland and individual oak trees
Biological Resources - Water	3B.3-2	Loss and degradation of habitat for special-status wildlife species and potential direct take of individuals
Climate Change - Land	3A.4-1	Generation of temporary, short-term construction-related GHG emissions
	3A.4-2	Generation of long-term operational GHG emissions
Climate Change - Water	3B.4-1	Net Increase in Greenhouse Gases
Geology, Soils, Minerals, and Paleontological Resources - Land	3A.7-9	Possible loss of mineral resources – kaolin clay
Land Use and Agricultural Resources - Land	3A.10-3	Cancellation of existing on-site Williamson Act contracts
	3A.10-4	Potential conflict with existing off-site Williamson Act contracts
Land Use and Agricultural Resources - Water	3B.10-2	Conflict with applicable local agency land use plans, policies, or regulations.
	3B.10-4	Cancellation of existing on-site Williamson Act contracts
Noise - Land	3A.11-1	Temporary, Short-Term Exposure of Sensitive Receptors to Increased Equipment Noise from Project Construction
	3A.11-3	Temporary, Short-Term Exposure of Sensitive Receptors to Potential Groundborne Noise and Vibration from Project Construction
	3A.11-4	Long-Term Exposure of Sensitive Receptors to Increased Traffic Noise Levels from Project Operation
Noise - Water	3B.11-1	Temporary, short-term exposure of sensitive receptors to increased equipment noise from project construction
	3B.11-3	Permanent increase in ambient noise levels
Traffic and Transportation - Land	3A.15-1d	Unacceptable LOS at the Scott Road (North)/Easton Valley Parkway intersection (Intersection 38)
	3A.15-2	Increased demand for single-occupant automobile travel in the project area

Table 4-9 Summary of Project-Related Significant and Unavoidable Impacts		
Section Name/Issue Area/Project Component	**Impact Number**	**Impact Title**
Utilities and Service Systems - Land	3A.16-3	Increased demand for SRWTP wastewater treatment plant facilities – indirect contribution to significant and unavoidable air quality impact from expansion of treatment plant
	3A.16-4	Increased demand for EID off-site wastewater collection and conveyance facilities – potential direct and indirect contribution to need for new EID collection and conveyance facilities, the environmental effects of which are presently unknown
	3A.16-5	Increased demand for EID wastewater treatment plant facilities - potential direct and indirect contribution for need for EID plant expansion, the environmental effects of which are presently unknown
Notes: NA = no analysis; ROG = reactive organic gases; NO_X = oxides of nitrogen; PM_{10} = respirable particulate matter less than ten microns in diameter, and $PM_{2.5}$ = particulate matter 5 micrometers or less; GHG = greenhouse gases; SACOG = Sacramento Area Council of governments; LOS = level of service; SRWTP = Sacramento Regional Wastewater Treatment Plant; EID = El dorado Irrigation District Source: Data compiled by AECOM in 2010		

The detailed discussion of specific significant and unavoidable impacts below follows the issue areas, impacts, and "Land" or "Water" portions of the EIR/EIS that are identified in Table 4-9. If no significant and unavoidable impacts would occur, that topic or that portion of the EIR/EIS is not discussed below.

4.5.1 AESTHETICS - LAND

The SPA consists of a flow from oak woodlands, to gently rolling grasslands, to steep vegetation-covered hillsides. Because the SPA contains high levels of vividness, intactness, and unity, and due to its location along U.S. 50 where it is seen by thousands of motorists, viewer sensitivity is considered to be high. Project implementation would substantially alter the existing scenic vista in the SPA, from open grazing land to urban development (Impact 3A.1-1). No feasible mitigation measures are available to reduce impacts associated with the alteration of scenic vistas from project development to a less-than-significant level. Therefore, this impact would be significant and unavoidable.

Scott Road south of White Rock Road is a designated scenic corridor in Sacramento County, because the existing grasslands and cattle-grazing lands are considered exemplary views of the rural Sacramento County landscape. Project implementation would substantially damage views from the portion of Scott Road designated as a scenic corridor because the rural landscape on Scott Road north of White Rock Road, which would be visible from the scenic corridor, would be replaced with urban land uses (Impact 3A.1-2). No feasible mitigation measures are available to reduce impacts associated with the damage to the scenic resources visible on the designated scenic corridor from project development to a less-than-significant level. Therefore, this impact would be significant and unavoidable.

Project implementation would substantially degrade the visual character of the SPA through conversion of grazing land to developed urban uses (Impact 3A.1-3). Because of the large scale and location of the SPA (visible by a large number of viewers along U.S. 50 and within the City of Folsom), there is no feasible mitigation available to fully reduce visual resource impacts associated with the conversion of a large expanse of agricultural land to urban development. Therefore, this impact would be significant and unavoidable.

The presence and movement of heavy construction equipment and staging areas would temporarily degrade the existing visual character and/or quality of the SPA and surrounding area (Impact 3A.1-4). Project implementation would involve four phases of similar types of construction over a 19-year phased buildout period (for information on project phasing, please refer to Section 2.3.1 in Chapter 2, "Alternatives"). During this time, adjacent project

development, including sensitive land uses such as housing, schools, and parks, would be occupied while construction is occurring in a different phase. Construction areas would also be visible to motorists and employees of existing businesses. As required by Mitigation Measure 3A.1-4, the project applicant(s) of all project phases would locate staging and material storage areas as far away from sensitive land uses (i.e., residential areas, schools, parks) developed in earlier development phases, and would provide visual screening, to the maximum extent practicable. However, because screening may not always be feasible (e.g., projects covering a large area or tall buildings), this temporary impact would be significant and unavoidable.

Project implementation would require lighting of new development that could inadvertently cause increased skyglow effects, effectively obscuring views of stars, constellations, and other features of the night sky (Impact 3A.1-6). Implementation of Mitigation Measure 3A.1-5 would partially reduce significant impacts associated with effects from skyglow. However, because of the scale and location of the SPA, these lighting guidelines would not fully reduce new skyglow effects to a less-than-significant level. Therefore, project-related skyglow impacts would be significant and unavoidable.

4.5.2 AIR QUALITY - LAND

Construction activities associated with the project would generate intermittent emissions of NO_X and PM_{10}. Because of the large size of the project, construction-generated emissions of NO_X, an ozone precursor, and fugitive PM_{10} dust would exceed SMAQMD-recommended thresholds and would substantially contribute to emissions concentrations that exceed the NAAQS and CAAQS. Also, project-generated construction-related emissions of ROG could exceed EDCAQMD-recommended thresholds for construction of the two off-site roadway extensions from Folsom Heights into El Dorado Hills. Thus, project-generated, construction-related emissions of criteria air pollutants and precursors could violate or contribute substantially to an existing or projected air quality violation, expose sensitive receptors to substantial pollutant concentrations, and/or conflict with air quality planning efforts (Impact 3A.2-1). Implementation of Mitigation Measures 3A.2-1a and 3A.2-1d would reduce NO_X emissions to levels below the applicable thresholds. However, generation of PM_{10} from on-site construction activities, and generation of PM_{10} from the off-site U.S. 50 interchange improvements and the Rowberry Drive Overcrossing, could potentially exceed or contribute substantially to exceedances of the CAAQS and NAAQS at nearby receptors even after implementation of Mitigation Measures 3A.2-1a, 3A.2-1b, 3A.2-1c, 3A.2-1e, and 3A.2-1f. Because no other feasible mitigation measures are available to reduce project-generated construction-related PM_{10} emissions, this impact would be significant and unavoidable.

Operational area- and mobile-source emissions from project implementation would exceed the SMAQMD-recommended threshold of 65 lb/day for ROG and NO_X, and would result in or substantially contribute to emissions concentrations that exceed the NAAQS or CAAQS. In addition, because of the large increase in emissions associated with project build out and the fact that the project is not within an already approved plan (which means that increased emissions would not already be accounted for in applicable air quality plans), project implementation could conflict with air quality planning efforts in the SVAB (Impact 3A.2-2). Implementation of Mitigation Measure 3A.2-2 would reduce ROG and NO_X emissions associated with operation of the project. As described in detail in Impact 3A.2-2, even if operational emissions of NO_X were 35% lower than the levels reported in Tables 3A.2-6 through 3A.2-10 (to account for differences in modeling output and the required air quality mitigation plan), they would still exceed SMAQMD's significance threshold of 65 lb/day. As a result, this impact would be significant and unavoidable.

Project implementation would result in exposure of sensitive receptors to short- and long-term emissions of TACs from on-site stationary and mobile sources and from off-site mobile sources (Impact 3A.2-4). Implementation of Mitigation Measure 3A.2-4 would lessen health-related risks associated with the operation of off-road diesel powered equipment during construction activity and would lessen health-related risks associated with mobile-source TACs; however, TAC exposure levels would not necessarily be reduced to less-than-significant levels. Because no additional feasible mitigation measures are available, exposure to mobile-source TAC emissions from on-site mobile sources therefore would be a significant and unavoidable impact. This conclusion has been reached

due to the uncertainty about the potential TAC emission sources associated with on-site commercial and industrial land use activities and the proximity of sensitive receptors to such uses. In addition, there is also uncertainty about the feasibility and effectiveness of extending the setback distances between roadways and receptors and the effectiveness and feasibility of tiered planting of fine-needle tree species. Therefore, this conclusion may change as more detailed information regarding proposed on-site commercial uses becomes available and analyses of individual phases are performed at the project level.

Project construction activities associated with the development of on-site land uses could result in odorous emissions from diesel exhaust generated by construction equipment. During some periods of the 19-year buildout of the project intense levels of construction activity could potentially occur in close proximity to existing or future-planned sensitive receptors or construction activity could potentially occur near sensitive receptors for an extended period of time. In particular, a substantial number of people in the existing residential neighborhood that located just east of the SPA in El Dorado Hills could be exposed to odorous diesel exhaust emissions generated by on-site construction activity. Implementation of Mitigation Measure 3A.2-1a and Mitigation Measure 3A.2-1f would reduce the mass levels of odorous diesel exhaust during construction of the on-site elements. However, given that construction activity would occur in the SPA during the 19-year buildout of the project, generation of construction-generated diesel exhaust, particularly during periods of intense grading on the eastern hillside of the SPA, could expose a substantial number of people to odorous emissions and, therefore, this impact would not be reduced to a less-than-significant level. Therefore, the potential exposure of a substantial number of people to these objectionable odors is considered to be significant and unavoidable.

4.5.3 AIR QUALITY - WATER

Construction of the Off-Site Water Facility Alternatives could result in temporary and short-term, but significant and unavoidable impacts to air quality through the generation of criteria ozone precursors (e.g. NO_X). Even after the application of mitigation, residual construction-related direct and indirect air quality impacts would be significant for the Preferred Off-Site Water Facility Alternative and Off-Site Water Facility Alternatives 1, 1A, 3, 3A, 4, and 4A. Due to the substantially smaller footprint of the Off-Site Water Faculties under Alternative 2, 2A, and 2B, residual construction-related ozone impacts would be less-than-significant without mitigation. Only minor quantities of criteria air pollutants would be generated during the operation of all the Off-site Water Facility Alternatives and, therefore, the residual impact would be less-than-significant with no mitigation required.

4.5.4 BIOLOGICAL RESOURCES - LAND

Implementation of the project could result in the placement of fill material into Waters of the U.S., including wetlands subject to U.S. Army Corps of Engineers jurisdiction under the Federal Clean Water Act, and the potential loss and degradation of wetland habitats protected under state and local regulations (Impact 3A.3-1). Implementation of Mitigation Measure 3A.3-1a and 3A.3-1b would reduce significant direct and indirect impacts, but not to a less-than-significant level. Considering the rate of development in Sacramento County and the limited amount of undeveloped, unspoken for land that supports existing wetlands that could be preserved, or that is suitable for creation of compensatory aquatic habitats similar to those that would be removed by project implementation, it may not be possible to fully mitigate the loss of habitat functions and values provided by the nearly 45 acres of aquatic habitats that would be lost in the SPA. Therefore, the direct impact would be significant and unavoidable. Furthermore, a number of different project-related factors (described in Impact 3A.3-1) could substantially diminish the water quality, hydrologic, and habitat functions of all wetlands remaining on site and downstream in the project vicinity, therefore resulting in indirect impacts that would be significant and unavoidable

Project implementation would result in the loss and degradation of habitat for several special-status wildlife species. Take of several listed species, including vernal pool invertebrates, valley elderberry longhorn beetle, and Swainson's hawk, could also occur. (Impact 3A.3-2.) Implementation of Mitigation Measures 3A.3-2a, 3A.3-2b, 3A.3-2c, 3A.3-2d, 3A.3-2e would lessen significant direct and indirect impacts on special-status wildlife;

however, this impact would remain significant and unavoidable because the direct removal of approximately 2,700 acres and indirect effect to approximately 800 acres of potential habitat for special-status wildlife cannot be fully mitigated. Impacts on special-status wildlife species could be fully mitigated only through a combination of habitat preservation and restoration in the vicinity of the SPA. Parcels of similar habitat quality are currently present in the project vicinity, but these parcels would be of lesser value following development of the project because of the effects of habitat fragmentation and secondary and indirect impacts related to the project. Moreover, there would be a net loss of approximately 3,500 acres of potential habitat for special-status species regardless of the acreage preserved. Therefore, fully compensating for the impact by preserving existing habitat in the project vicinity is infeasible. The mitigation does include elements of habitat creation and enhancement that would increase the habitat value of preserved lands so that mitigation habitat could be of greater value than habitat lost and degraded, but there is not sufficient undeveloped land in the project vicinity to offset the effects of habitat fragmentation on special-status species, and thus, fully mitigate the impact or reduce it to a less-than-significant level.

Project implementation would result in the removal of 444 acres of blue oak woodland and thousands of individual oak trees meeting the criteria for protection under Folsom Municipal Code and the Sacramento County Tree Ordinance (Impact 3A.3-5). Implementation of Mitigation Measure 3A.3-5 would reduce significant impacts from loss of blue oak woodland and protected trees, but not to a less-than-significant level because the loss of individual oak trees and blue oak woodland acreage and function would be extensive and would contribute substantially to the regional loss of this resource. It is unknown at this time if blue oak woodland habitat acreage having similar tree sizes and densities, species composition, site condition, and landscape context to the blue oak woodland to be removed would be available for purchase and preservation in perpetuity. Furthermore, planting replacement trees would result in temporal losses of oak tree resources until the replacement trees reached comparable sizes as the trees to be removed; a process that would take many decades, and it is unknown if a suitable site to plant thousands of trees and restore historic or existing blue oak woodland would be available in Sacramento County or even nearby in neighboring counties. Therefore, impacts on blue oak woodland and protected trees would remain significant and unavoidable.

4.5.5 BIOLOGICAL RESOURCES - WATER

Vernal pools, seasonal wetlands, and seasonal wetland swale are documented throughout Zone 4 of the "Water" Study Area, comprising approximately 10.8 acres, 7.8 acres, and 4.9 acres, respectively, and support special-status invertebrates such as vernal pool fairy shrimp and vernal pool tadpole shrimp. Other species may include California linderiella fairy shrimp (*Linderiella occidentalis*) or conservancy fairy shrimp (*Branchinecta conservatio*). As shown in Table 3B.3-5, vernal pool fairy shrimp and vernal pool tadpole shrimp are known to occur in the vicinity of all the Off-site Water Facility Alternatives that cross through Zone 4 of the "Water" Study Area. Depending on the location of the construction (i.e., roadway centerline verses shoulder) construction activities associated with the pipelines and WTPs could result in significant direct and indirect impacts to vernal pool habitat and, hence, vernal pool crustaceans. Impacts to vernal pool crustaceans species could only be mitigated through a combination of habitat preservation and restoration in the vicinity of the selected Off-site Water Facilities. Given that even following the restoration of the impacted area(s), the take of these species could have already occurred, the City is unable to demonstrate complete avoidance. Therefore, demonstrating full compensation for these impacts by preserving and restoring existing habitats for vernal pool crustaceans in the vicinity of the selected Off-site Water Facility Alternative is infeasible. For this reason, the direct and indirect impacts would remain significant and unavoidable.

4.5.6 CLIMATE CHANGE - LAND

Project implementation would result in increased generation of GHGs, which could contribute to global climate change on a cumulative level. The project would contribute to cumulatively considerable GHG emissions in both the short term and the long term (Impacts 3A.4-1 and 3A.4-2).

Implementation of Mitigation Measures 3A.2-1 and 3A.4-1 would partially reduce GHG emissions from short-term GHG emissions associated with construction activity. Because this analysis is conducted at a program level and the project would be constructed in phases over a 19-year period (for information on project phasing, please refer to Section 2.3.1 in Chapter 2, "Alternatives"), the extent to which feasible technologies and GHG reduction measures will continue to be developed is not known at the time of writing this EIR/EIS. Therefore, this analysis concludes that the reductions achieved by implementing Mitigation Measures 3A.2-1 and 3A.4-1 would not be sufficient to fully reduce the construction-generated GHGs to the extent that they would not be cumulatively considerable.

Although implementation of Mitigation Measures 3A.2-2, 3A.4-2, and 3A.4-3 would reduce the project's incremental contribution to long-term operational GHG emissions, it is unknown at the time of writing this EIR/EIS whether the selected project-specific measures during each project phase, in combination with the GHG reductions realized from the regulatory environment that exists at that time, would result in attainment of the applicable CO_2e/SP goal. Therefore, the project's long-term contribution of operational GHG emissions is considered potentially significant and unavoidable.

4.5.7 CLIMATE CHANGE - WATER

Based on a quantification of the Offsite Water Facility Alternatives' energy requirements to support conveyance, treatment, and local distribution operations at build-out of the Folsom Specific Plan, the Offsite Water Facility Alternatives are expected to indirectly generate substantial emissions of GHGs. Even with the application of the prescribed mitigation, the collective measures are not expected to reduce Offsite Water Facilities-related GHG emissions below the applied threshold and, therefore, this impact is considered significant and unavoidable.

4.5.8 GEOLOGY, SOILS, MINERALS, AND PALEONTOLOGICAL RESOURCES - LAND

The SPA is located within the Sacramento-Fairfield Production-Consumption Region designated by CDMG and may contain a deposit of kaolin clay (Impacts 3A.7-9 and 3A.7-19). The western edge of the SPA is zoned MRZ-3 for kaolin clay. This classification was applied by CDMG because that area roughly corresponds to the location of the Ione Formation in the SPA. The Ione Formation is known to contain kaolin clay in other locations in northern California. Implementation of Mitigation Measure 3A.7-9 would provide data that would allow the project applicant(s) and the lead agencies to determine whether or not economically valuable mineral resources are present in the MRZ-3 kaolin clay area of the SPA. However, if economically valuable mineral resources were found to be present, they would be covered over with urban land uses as a result of project development, and would no longer be available for mining. Therefore, this impact is considered potentially significant and unavoidable, because there are no feasible mitigation measures available to avoid or reduce this impact to a less-than-significant level.

4.5.9 LAND USE AND AGRICULTURAL RESOURCES - LAND

Approximately 1,530 acres of the SPA consist of agricultural lands under existing Williamson Act contracts. Notices of nonrenewal were filed on these parcels in 2004 and 2006; as a result, these existing contracts will expire in 2014 and 2016, respectively. However, project implementation would require the cancellation of one or more of these Williamson Act contracts before their expiration date because the proposed land uses would not be permitted under the existing contracts (Impacts 3.10-3 and 3.10-7). No feasible mitigation measures are available to reduce impacts associated with the cancellation of these Williamson Act contracts to a less-than-significant level. Therefore, this impact would be significant and unavoidable.

Project implementation could conflict with lands under Williamson Act contracts south of the SPA; thereby potentially resulting in indirect impacts related to cancellation of those contracts (Impact 3.10-4). Land south of the SPA is characterized primarily by seasonal grazing land in an unincorporated area regulated by Sacramento County, outside of the Urban Service Boundary, and the majority of these lands are under Williamson Act

contracts. Land uses inconsistent with Williamson Act provisions and resulting in subsequent contract non-renewals could occur through requests for general plan amendments and rezoning of these lands as a result of indirect pressure to develop from implementation of the project. No feasible mitigation measures are available to reduce impacts associated with conflicts or cancellation of these Williamson Act contracts on adjacent land to a less-than-significant level. Therefore, this impact would be potentially significant and unavoidable.

Several impacts of the proposed GPA would remain significant and unavoidable after implementation of all feasible mitigation, including aesthetics, air quality, climate change, noise, population and housing, traffic, and water supply. These significant and unavoidable impacts would be similar to those described for the "Land" portion of the project throughout Section 4.5.

4.5.10 LAND USE AND AGRICULTURAL RESOURCES - WATER

Implementation of Mitigation Measure 3B.10-1 could reduce potentially significant impacts related to inconsistencies with existing land use policies and plans under Off-site Water Supply Alternatives 1, 1A, 3, 3A, 4 and 4A to a less-than-significant level by requiring use permits or annexation to the City prior to the construction and operation of the White Rock and Folsom Boulevard WTPs. However, given that discretionary approval conflict would by required by either LAFCo or the corresponding local jurisdiction (e.g. Sacramento County), the City is unable to guarantee that the prescribed mitigation measure reduce inconsistencies associated with potential conflicts with LAFCo's policies and Sacramento County's USB to a less-than-significant level. Therefore, this impact remains potentially significant and unavoidable for Off-site Water Facility Alternatives 1, 1A, 3, and 3A, 4 and 4A.

Implementation of Off-site Water Facilities Alternatives PA, 1, 1A, 3, and 3A could conflict with lands under Williamson Act contracts; thereby potentially resulting in indirect impacts related to cancellation of those contracts (Impacts 3B.10-4). Land uses inconsistent with Williamson Act provisions and resulting in subsequent contract non-renewals could occur through annexation and rezoning of these lands as a result of indirect pressure to develop from implementation of the project. No feasible mitigation measures are available to reduce impacts associated with conflicts or cancellation of these Williamson Act contracts on adjacent land to a less-than-significant level. Therefore, this impact would be potentially significant and unavoidable.

4.5.11 NOISE - LAND

Implementation of mitigation measures contained in Section 3A.11, "Noise - Land " would reduce impacts associated with (1) temporary, short-term exposure of sensitive receptors to increased equipment noise from project construction in all locations except as related to the off-site roadway connections in El Dorado Hills. Sensitive receptors along those El Dorado Hills roadway connections would be exposed to noise levels that would still exceed applicable thresholds even after implementation of all feasible mitigation, and therefore a significant and unavoidable impact would occur. Implementation of mitigation measures contained in Section 3A.11, "Noise - Land " would also reduce impacts associated with groundborne noise and vibration from project construction, and the long-term exposure of sensitive receptors to increased operational traffic noise levels from project operation, but not to a less-than-significant level, because noise levels would (or could potentially) still exceed applicable thresholds and, therefore, residual significant impacts would occur. All other noise impacts would be reduced to a less-than-significant level following implementation of the recommended mitigation measures.

Additionally, some of the off-site elements fall under the jurisdiction of El Dorado and Sacramento Counties and/or Caltrans; therefore, neither the City nor the project applicant(s) would have control over their timing or implementation. Therefore, the impacts related to those off-site facilities that are under the jurisdiction of El Dorado County, Sacramento County, or Caltrans, are considered potentially significant and unavoidable. If El Dorado County, Sacramento County, and Caltrans cooperate in implementation of the recommended mitigation measures, then those impacts would be reduced to a less-than-significant level.

4.5.12 NOISE - WATER

Although implementation of the recommended mitigation measures would generally reduce construction noise, construction-related noise levels could occasionally exceed the Sacramento County and City of Rancho Cordova standards regarding construction noise. Although there are smaller number of receptors potentially affected under Off-site Water Facility Alternatives PA, 1, 1A, 4, and 4A, implementation of the recommended mitigation would not reduce construction-related noise impacts to a less-than-significant level at these locations. In addition, construction activities at the pump station facility may occur over a more extended period of time, up to several months, and could contribute to noises levels in excess of 80 dBA. These impacts could remain significant and unavoidable, because there is no feasible mitigation to fully reduce temporary, short-term construction-related impacts to a less-than-significant level. Based on the larger number of receptors affected along the conveyance alignments, construction-related noise impacts under Off-site Water Facility Alternatives 2, 2A, 2B, 3, and 3A could also remain significant and unavoidable to these residential centers, because there is no feasible mitigation to fully reduce temporary, short-term construction-related impacts to a less-than-significant level.

The operation of the pumps and generators for Off-Site Water Facilities pump stations and WTP facilities could occur within close proximity of sensitive receptors, thereby resulting in a permanent increase in noise levels. Although the City has identified a series of mitigation measures discussed in Section 3B.11, "Noise - Water" to address potential long-term impacts to adjacent sensitive receptors, given uncertainties regarding the design of these facilities and their respective locations, the City is unable to confirm whether the mitigation imposed would be effective in reducing long-term noise to a less-than-significant level. For this reason, long-term, residual noise impacts from these facilities under Off-site Water Facility Alternatives PA, 1, 1A, 3, 3A, 4, and 4A could be significant and unavoidable.

4.5.13 TRAFFIC AND TRANSPORTATION - LAND

Implementation of the proposed project or the alternatives would result in significant impacts to numerous intersections and roadways. However, mitigation measures, including construction of roadway and intersection improvements, would reduce all but five of these impacts to a less-than-significant level. Two intersection impacts, at Oak Avenue Parkway / East Bidwell Street and East Bidwell Street / Iron Point Road would remain significant and unavoidable because it is contrary to City policy to construct 8-lane roadways, as would be required to fully mitigate the impact. Impacts to three roadway segments on eastbound U.S. 50, including the Zinfandel Drive to Sunrise Boulevard segment, the Rancho Cordova Parkway to Hazel Avenue segment, and the Folsom Boulevard to Prairie City Road segment, would remain significant and unavoidable. The mitigation measures proposed for these segments call for fair-share payments to support the construction of the Southeast Capitol Connector. However, based on available information it cannot be determined that the proposed Southeast Capitol Connector will reduce traffic volumes on U.S. 50 to an acceptable LOS, and so these impacts are considered significant and unavoidable in this document.

Project implementation would increase demand for single-occupant automobile travel on area roadways and intersections causing roadway and intersection impacts (Impact 3.15-2). Implementation of Mitigation Measure 3.15-2a would reduce the demand of the single-occupant vehicle on area roadways and intersections. Implementation of Mitigation Measures 3.15-2b, 3.15-2c, and 3.15-2d would promote usage of alternative transportation modes and increase the supply of these modes. Although implementation of these mitigation measures have the potential to substantially reduce the number of single-occupant vehicles, the project would still to add a large number of single-occupant vehicles in the area. Because there are no additional feasible mitigation measures to further reduce the number of project-generated single-occupant vehicle trips, the impact would be significant and unavoidable.

4.5.14 UTILITIES AND SERVICE SYSTEMS - LAND

Project implementation would result in increased demand for treatment at the SRWTP (Impact 3.16-3). Implementation of Mitigation Measure 3.16-3 would ensure that sufficient wastewater treatment capacity is available to all project phases. However, SRCSD has identified the need for expansion of the SRWTP in the 2020 Master Plan approved in 2004. Because implementing the project would contribute to the need to expand the SRWTP facility, it would contribute directly and indirectly to impacts identified in the *Sacramento Regional Wastewater Treatment Plant 2020 Master Plan Final Environmental Impact Report* (2020 Master Plant EIR). Implementation of mitigation measures contained in the 2020 Master Plan EIR would reduce impacts in all but one issue area to a less-than-significant level. The 2020 Master Plan EIR identified the following significant and unavoidable impact:

- air quality: emissions of NO_X during construction.

Implementation of mitigation measures to reduce impacts is the responsibility of SRCSD; such measures would be implemented in accordance with the 2020 Master Plan EIR. However, this air quality impact related to the treatment plant expansion would be significant and unavoidable after implementation of all feasible mitigation measures, and the project would contribute to this significant and unavoidable impact.

Approximately 189 acres of the SPA are within the service area of EID, and would require off-site wastewater collection and conveyance facilities to the EID treatment plant (Impact 3.16-4). Implementation of Mitigation Measure 3.16-4 would reduce significant impacts associated with increased demand for EID off-site wastewater collection facilities to a less-than-significant level because adequate EID off-site wastewater conveyance facilities would be documented or adequate financing would be secured before approval final maps and issuance of building permits. However, it is unknown if existing collection and conveyance facilities have the capacity to accommodate wastewater flows generated by project development and the project could directly and indirectly contribute to the need for off-site EID wastewater facility improvements. Therefore, the project would contribute to the potentially significant environmental effects associated with improvements to these facilities for which feasible mitigation may not be available to reduce impacts to a less-than-significant level. Therefore, this would be a potentially significant and unavoidable impact.

Collected wastewater flows from the 189-acre EID portion of the SPA would ultimately be transported to the El Dorado Hills WWTP for treatment and disposal. Because the SPA was not included in the planned future capacity of the El Dorado Hills WWTP, the project would potentially result in increased in wastewater flows that exceed treatment plant capacity (Impact 3.16-5). Implementation of Mitigation Measure 3.16-5 would reduce significant impacts associated with increased demand for wastewater treatment plant facilities to a less-than-significant level because adequate wastewater treatment facilities would be documented before approval final maps and issuance of building permits. However, it is unknown if the existing El Dorado Hills WWTP has the capacity to accommodate wastewater flows generated by project development, and the project could directly and indirectly contribute to the need for El Dorado Hills WWTP improvements. Improvements at the treatment plant would require additional analysis in a separate CEQA document to identify specific impacts and any required mitigation measures. Impacts resulting from improvements to the El Dorado Hills WWTP could include: temporary, short-term generation of criteria air pollutants, such as PM_{10} and emissions of ozone precursors (e.g., ROG and NO_X) during construction; generation of new odors from operation of expanded treatment plant facilities; degradation of water quality from increased discharges to Carson Creek; temporary roadway lane closures, increased truck traffic, and other roadway impacts during construction; exposure of sensitive receptors to noise levels above noise ordinances during construction; and exposure of construction crews and the public to hazardous materials used in construction. It is unknown whether feasible mitigation would be available to reduce these impacts to a less-than-significant level. Therefore, this would be a potentially significant and unavoidable impact.

4.5.15 OFF-SITE IMPROVEMENTS RELATED TO "LAND" DEVELOPMENT THAT ARE NOT UNDER LEAD AGENCY JURISDICTION

This EIR/EIS identifies several project-related off-site land improvements associated with development of the SPA that are not under the jurisdiction of either of the co-lead agencies (City of Folsom and USACE) but are under the jurisdiction of several "responsible agencies" as defined under PRC Section 21069. Those improvements are presented in Table 4-10, below.

Table 4-10
Improvements that are Outside the Co-Lead Agencies' Jurisdiction

Improvement	Jurisdiction
U.S. 50 interchanges	California Department of Transportation
Roadway and sewer force main extensions from Folsom Heights into El Dorado Hills	El Dorado County Development Services Department
Detention basin west of Prairie City Road	Sacramento County Planning and Community Development Department

Note: See Chapter 1.0, "Introduction," for a complete list of project-related trustee, responsible, and cooperating agencies.
Source: Data compiled by AECOM in 2009

The EIR/EIS contains the following mitigation measures applied to off-site "Land" development improvements that would require implementation by one or more of the responsible agencies listed in Table 4-10 and therefore are outside of the control of the City or USACE:

- Aesthetics: 3A.1-4 and 3A.1-5.
- Air Quality: 3A.2-1a, 3A.2-1c, 3A.2-1d, 3A.2-1f, 3A.2-4, and 3A.2-5.
- Biological Resources: 3A.3-1a, 3A.3-1b, 3A.3-2a, 3A.3-2b, 3A.3-2c, 3A.3-2d, 3A.3-2e, 3A.3-2g, 3A.3-2h, 3A.3-3, 3A.3-4a, and 3A.3-5.
- Climate Change: 3A.4-1.
- Cultural Resources: 3A.5-1b, 3A.5-2, and A3A.5-3.
- Geology, Soils, Minerals, and Paleontological Resources: 3A.7-1a, 3A.7-1b, 3A.7-3, 3A.7-4, 3A.7-5, and 3A.7-10.
- Hazards and Hazardous Materials: 3A.8-2, 3A.8-3a, 3A.8-3b, 3A.8-3c, 3A.8-5, and 3A.8-7.
- Hydrology and Water Quality: 3A.9-1, 3A.9-2, 3A.9-3, and 3A.9-5.
- Noise: 3A.11-1, 3A.11-2, 3A.11-3, 3A.11-4, and 3A.11-5.
- Public Services: 3A.14-1.
- Traffic and Transportation: 3A.15-1g, 3A.15-1h, 3A.15-1i, 3A.15-1j, 3A.15-1k, 3A.15-1l, 3A.15-1m, 3A.15-1n, 3A.15-1o, 3A.15-1p, 3A.15-1q, 3A.15-1r, 3A.15-1s, 3A.15-1t, 3A.15-1u, 3A.15-1v, 3A.15-1w, 3A.15-1x, 3A.15-1y, 3A.15-1z, 3A.15-1aa, 3A.15-1bb, and 3.15-1cc.

Mitigation for these off-site elements that are outside of the City of Folsom's jurisdictional boundaries and must be coordinated by the project applicant(s) of each applicable project phase with the affected oversight agency(ies).

However, neither the City/USACE nor the project applicant(s) would have control over their timing or implementation; therefore, these impacts for which the co-lead agencies do not have control over mitigation are considered potentially significant and unavoidable. If the responsible agency(ies) implement the required mitigation, then the impact(s) would be reduced to a less-than-significant level.

4.5.16 CUMULATIVELY CONSIDERABLE IMPACTS

As discussed in detail in Section 4.1, "Cumulative Impacts" above, and in Sections 3A.15 and 3B.15, "Traffic and Transportation," project implementation would result in direct and indirect cumulatively considerable incremental contributions to significant adverse cumulative impacts. Those impacts are summarized below.

AESTHETICS

- Substantial alteration of a scenic vista - "Land"
- Substantial degradation of visual character - "Land"
- Substantial damage to the viewshed of a designated scenic corridor - "Land"
- New skyglow effects - "Land" and "Water"

AIR QUALITY

- Exposure of on-site sensitive receptors to TACs from high traffic volumes on local roadways (including quarry truck trips) - "Land"
- Exposure of on-site sensitive receptors to odorous exhaust emissions generated by equipment at the proposed City corporation yard - "Land"
- Exposure of new residents to odorous emissions - "Land"

BIOLOGICAL RESOURCES

- Loss or fill of wetlands and other Waters of the U.S., including wetlands and Waters of the State - "Land" and "Water"
- Loss or modification of sensitive natural habitats - "Land" and "Water"
- Decline of special-status plant and animal species in the region - "Land" and "Water"
- Degradation of wildlife habitat - "Land"
- Loss of blue oak woodland - "Land"
- Loss of annual grassland - "Land"

CLIMATE CHANGE

- Temporary, short-term construction-related generation of greenhouse gases - "Land" and "Water"
- Long-term operation-related generation of greenhouse gases - "Land"

CULTURAL RESOURCES

- Loss of known and unknown prehistoric and historic-era cultural sites - "Land" and "Water"

LAND USE AND AGRICULTURAL RESOURCES

- Cancellation of Williamson Act contracts - "Land"

NOISE

- Temporary, short-term exposure of sensitive receptors to noise - "Land" and "Water"
- Temporary, short-term exposure of sensitive receptors to potential groundborne noise and vibration - "Land" and "Water"
- Long-term exposure of sensitive receptors to increased traffic noise levels - "Land"

TRAFFIC AND TRANSPORTATION

- Lack of funding through City's Transportation Impact Fee Program - "Land"
- Increases to peak-hour and daily traffic volumes resulting in unacceptable levels of service (City of Folsom, Sacramento County, El Dorado County, Caltrans) - "Land" and "Water"

UTILITIES AND SERVICE SYSTEMS

- Contribution to presently unknown environmental impacts associated with EID sewer conveyance upgrades - "Land"
- Contribution to presently unknown environmental impacts associated with EID wastewater treatment plant upgrades - "Land"
- Contribution to significant and unavoidable air quality impact from expansion of SRWTP identified in 2020 Master Plan EIR - "Land"

Lisa Clay, J.D. ..... Assistant District Counsel
J.D.; 15 years of experience

AECOM

Francine Dunn ..... Principal/Project Manager
B.A.; 25 years of experience

Wendy Copeland ..... Co-Project Manager
B.S., M.S.; 11 years of experience — Geology, Soils, Minerals, and Paleontological Resources

Drew Sutton, AICP ..... Assistant Project Manager
B.A., M.C.R.P.; 9 years of experience — Hazards and Hazardous Materials

Mike Aviña ..... Cultural Resources, Climate Change
B.A., J.D., 14 years of experience

Tammie Beyerl ..... Botany and Wetland Resources
B.A., M.S.; 7 years of experience

Ted Daum ..... Hydrology and Water Quality
B.S., M.S.; 21 years of experience

Suzanne Enslow ..... Parks and Recreation
B.A.; 11 years of experience

Chris Fitzer ..... Hydrology and Water Quality
B.A., M.U.R.P.; 14 years of experience

Jenifer King ..... Population, Employment, and Housing; Environmental Justice;
B.S.; 12 years of experience — Land Use and Agriculture; Utilities and Service Systems; Public Services; Growth; Cumulative

Marianne Lowenthal ..... Aesthetic Resources, Hazards and Hazardous Materials
B.S.; 5 years of experience

George Lu ..... Air Quality, Climate Change
B.S.; 5 years of experience

Brian Ludwig..... Cultural Resources
B.A., M.A., Ph.D.; 28 years of experience

Melinda Rivasplata.....Parks and Recreation
B.A.; 21 years of experience

Chris Shields..... Noise
B.A., 5 years of experience

Lisa Clement..... GIS
B.S.; 9 years of experience

Christopher Donohue..... GIS
B.A.; 5 years of experience

Lorrie Jo Williams..... Graphics
B.S.; 12 years of experience

Brian Perry ..... Graphics
24 years of experience

Deborah Jew .....Publishing
A.A.; 22 years of experience

Gayiety Lane .....Publishing
A.A.; 11 years of experience

DKS ASSOCIATES TRANSPORTATION CONSULTANTS

John Long, P.E. .....Principal-in-Charge
B.S., M.S.; 33 years of experience

Kevin Stankiewicz, P.E. ..... Project Manager/Transportation Engineer
B.S., 10 years of experience

Victor Maslanka, P.E.....Quality Review/Senior Engineer
B.S., M.S.; 30 years of experience

Binu Abraham .....Transportation Engineer
B.S., M.S.; 8 years of experience

Lynda Tang, P.E.....Transportation Engineer
B.S., 5 years of experience

Britt Fugitt .....Transportation Engineer
B.S., 3 years of experience

RMC WATER AND ENVIRONMENT

Steve Brown ..... Project Manager for “Water” Analysis
B.S., 20 years of experience

Clint T. Meyer ..... Task Leader/Senior Environmental Scientist for “Water” Analysis
B.S., 12 years of experience

Robin Cort ..... QA/QC Leader for “Water” Analysis
B.S., Ph.D., 25 years of experience

Suet Chau .....Senior Environmental Planner for “Water” Analysis
B.S., 10 years of experience

Chris van Lienden.....Engineering/GIS
B.S., P. E., 4 years of experience
